

# [MS-PST]: Outlook Personal Folders File Format (.pst) Structure Specification

---

## Intellectual Property Rights Notice for Open Specifications Documentation

- **Technical Documentation.** Microsoft publishes Open Specifications documentation for protocols, file formats, languages, standards as well as overviews of the interaction among each of these technologies.
- **Copyrights.** This documentation is covered by Microsoft copyrights. Regardless of any other terms that are contained in the terms of use for the Microsoft website that hosts this documentation, you may make copies of it in order to develop implementations of the technologies described in the Open Specifications and may distribute portions of it in your implementations using these technologies or your documentation as necessary to properly document the implementation. You may also distribute in your implementation, with or without modification, any schema, IDL's, or code samples that are included in the documentation. This permission also applies to any documents that are referenced in the Open Specifications.
- **No Trade Secrets.** Microsoft does not claim any trade secret rights in this documentation.
- **Patents.** Microsoft has patents that may cover your implementations of the technologies described in the Open Specifications. Neither this notice nor Microsoft's delivery of the documentation grants any licenses under those or any other Microsoft patents. However, a given Open Specification may be covered by Microsoft's Open Specification Promise (available here: <http://www.microsoft.com/interop/osp>) or the Community Promise (available here: <http://www.microsoft.com/interop/cp/default.mspx>). If you would prefer a written license, or if the technologies described in the Open Specifications are not covered by the Open Specifications Promise or Community Promise, as applicable, patent licenses are available by contacting [iplg@microsoft.com](mailto:iplg@microsoft.com).
- **Trademarks.** The names of companies and products contained in this documentation may be covered by trademarks or similar intellectual property rights. This notice does not grant any licenses under those rights.
- **Fictitious Names.** The example companies, organizations, products, domain names, e-mail addresses, logos, people, places, and events depicted in this documentation are fictitious. No association with any real company, organization, product, domain name, email address, logo, person, place, or event is intended or should be inferred.

**Reservation of Rights.** All other rights are reserved, and this notice does not grant any rights other than specifically described above, whether by implication, estoppel, or otherwise.

**Tools.** The Open Specifications do not require the use of Microsoft programming tools or programming environments in order for you to develop an implementation. If you have access to Microsoft programming tools and environments you are free to take advantage of them. Certain Open Specifications are intended for use in conjunction with publicly available standard specifications and network programming art, and assumes that the reader either is familiar with the aforementioned material or has immediate access to it.

# Table of Contents

<b>1 Introduction .....</b>	<b>10</b>
1.1 Glossary .....	10
1.2 References.....	11
1.2.1 Normative References.....	11
1.2.2 Informative References .....	11
1.3 Structure Overview .....	11
1.3.1 Logical Architecture of a PST File.....	12
1.3.1.1 The Node Database (NDB) Layer .....	12
1.3.1.2 The Lists, Tables, and Properties (LTP) Layer .....	13
1.3.1.2.1 Heap-on-Node (HN).....	13
1.3.1.2.2 BTree-on-Heap (BTH) .....	13
1.3.1.3 The Messaging Layer.....	14
1.3.2 Physical Organization of the PST File Format.....	14
1.3.2.1 Header .....	14
1.3.2.1.1 Metadata and State of the PST File .....	14
1.3.2.1.2 Root Record .....	15
1.3.2.1.3 Initial Free Map (FMap) and Free Page Map (FPMMap).....	15
1.3.2.2 Reserved Data .....	15
1.3.2.3 Density List (DList) .....	15
1.3.2.4 Allocation Map (AMap).....	15
1.3.2.5 Page Map (PMap).....	15
1.3.2.6 Data Section .....	15
1.3.2.7 Free Map (FMap) .....	16
1.3.2.8 Free Page Maps (FPMMap) .....	16
1.4 Relationship to Protocols and Other Structures .....	16
1.5 Applicability Statement.....	16
1.6 Versioning and Localization .....	16
1.7 Vendor-Extensible Fields.....	16
<b>2 Structures .....</b>	<b>17</b>
2.1 Property and Data Type Definitions .....	17
2.1.1 Data Types .....	17
2.1.2 Properties.....	17
2.2 NDB Layer .....	18
2.2.1 Fundamental Concepts.....	18
2.2.1.1 Nodes .....	18
2.2.1.2 ANSI Versus Unicode .....	19
2.2.2 Data Structures.....	19
2.2.2.1 NID (Node ID).....	19
2.2.2.2 BID (Block ID) .....	20
2.2.2.3 IB (Byte Index) .....	21
2.2.2.4 BREF.....	21
2.2.2.5 ROOT .....	22
2.2.2.6 HEADER .....	24
2.2.2.7 Pages.....	28
2.2.2.7.1 PAGETRAILER .....	28
2.2.2.7.2 AMap (Allocation Map) Page .....	30
2.2.2.7.2.1 AMAPPAGE.....	30
2.2.2.7.3 PMap (Page Map) Page .....	31
2.2.2.7.3.1 PMAPPAGE.....	31

2.2.2.7.4.1 DLISTPAGEENT .....	32
2.2.2.7.4.2 DLISTPAGE .....	33
2.2.2.7.5 FMap (Free Map) Page .....	34
2.2.2.7.5.1 FMAPPAGE .....	34
2.2.2.7.6 FPMMap (Free Page Map) Page .....	35
2.2.2.7.6.1 FPMAPPAGE .....	35
2.2.2.7.7 BTrees .....	35
2.2.2.7.7.1 BTPAGE .....	35
2.2.2.7.7.2 BTENTRY (Intermediate Entries) .....	37
2.2.2.7.7.3 BBTENTRY (Leaf BBT Entry) .....	38
2.2.2.7.7.3.1 Reference Counts .....	38
2.2.2.7.7.4 NBTENTRY (Leaf NBT Entry) .....	39
2.2.2.7.7.4.1 Parent NID .....	40
2.2.2.8 Blocks .....	40
2.2.2.8.1 BLOCKTRAILER .....	41
2.2.2.8.2 Anatomy of a Block .....	42
2.2.2.8.3 Block Types .....	42
2.2.2.8.3.1 Data Blocks .....	43
2.2.2.8.3.1.1 Data Block Encoding/Obfuscation .....	44
2.2.2.8.3.2 Data Tree .....	44
2.2.2.8.3.2.1 XBLOCK .....	44
2.2.2.8.3.2.2 XXBLOCK .....	45
2.2.2.8.3.3 Subnode BTree .....	47
2.2.2.8.3.3.1 SLBLOCKS .....	47
2.2.2.8.3.3.1.1 SLENTRY (Leaf Block Entry) .....	47
2.2.2.8.3.3.1.2 SLBLOCK .....	48
2.2.2.8.3.3.2 SIBLOCKS .....	49
2.2.2.8.3.3.2.1 SIENTRY (Intermediate Block Entry) .....	49
2.2.2.8.3.3.2.2 SIBLOCK .....	50
2.3 LTP Layer .....	52
2.3.1 HN (Heap-on-Node) .....	52
2.3.1.1 HID .....	52
2.3.1.2 HNHDR .....	52
2.3.1.3 HNPAGEHDR .....	54
2.3.1.4 HNBITMAPHDR .....	54
2.3.1.5 HNPAGEMAP .....	55
2.3.1.6 Anatomy of HN Data Blocks .....	56
2.3.1.6.1 Single-block Configuration .....	56
2.3.1.6.2 Data Tree Configuration .....	56
2.3.2 BTree-on-Heap (BTH) .....	57
2.3.2.1 BTHHEADER .....	57
2.3.2.2 Intermediate BTH (Index) Records .....	58
2.3.2.3 Leaf BTH (Data) Records .....	58
2.3.3 Property Context (PC) .....	59
2.3.3.1 Accessing the PC BTHHEADER .....	59
2.3.3.2 HNID .....	59
2.3.3.3 PC BTH Record .....	59
2.3.3.4 Multi-Valued Properties .....	60
2.3.3.4.1 MV Properties with Fixed-size Base Type .....	60
2.3.3.4.2 MV Properties with Variable-size Base Type .....	60
2.3.3.5 Anatomy of a PC .....	61
2.3.4 Table Context (TC) .....	62

2.3.4.1	TCINFO .....	63
2.3.4.2	TCOLDESC.....	65
2.3.4.3	The RowIndex .....	65
2.3.4.3.1	TCROWID.....	65
2.3.4.4	Row Matrix .....	66
2.3.4.4.1	Row Data Format .....	67
2.3.4.4.2	Variable-sized Data .....	68
2.3.4.4.3	Cell Existence Test .....	69
2.4	Messaging Layer .....	69
2.4.1	Special Internal NIDs .....	69
2.4.2	Properties.....	70
2.4.2.1	Standard Properties .....	70
2.4.2.2	Named Properties .....	70
2.4.2.3	Calculated Properties .....	71
2.4.3	Message store.....	71
2.4.3.1	Minimum Set of Required Properties .....	71
2.4.3.2	Mapping between EntryID and NID .....	71
2.4.3.3	PST Password Security .....	72
2.4.4	Folders.....	72
2.4.4.1	Folder object PC .....	73
2.4.4.1.1	Property Schema of a Folder object PC.....	73
2.4.4.1.2	Locating the Parent Folder object .....	73
2.4.4.2	Folder Template Tables .....	73
2.4.4.3	Data Duplication and Coherency Maintenance .....	74
2.4.4.4	Hierarchy Table .....	74
2.4.4.4.1	Hierarchy Table Template.....	74
2.4.4.4.2	Locating sub-Folder object Nodes .....	75
2.4.4.5	Contents Table .....	75
2.4.4.5.1	Contents Table Template.....	75
2.4.4.5.2	Locating Message object Nodes.....	77
2.4.4.6	FAI contents table .....	77
2.4.4.6.1	FAI contents table Template .....	77
2.4.4.7	Anatomy of a Folder Hierarchy .....	78
2.4.4.8	Implications of Modifying a Folder Template Table .....	79
2.4.4.9	Implications of Modifying a Folder object TC.....	79
2.4.5	Message objects.....	79
2.4.5.1	Message object PC.....	80
2.4.5.1.1	Property Schema of a Message object PC .....	81
2.4.5.2	Locating the Parent Folder object of a Message object .....	81
2.4.5.3	Recipient Table.....	81
2.4.5.3.1	Recipient Table Template .....	81
2.4.5.3.2	Message object Recipient Tables .....	82
2.4.6	Attachment objects .....	82
2.4.6.1	Attachment Table .....	82
2.4.6.1.1	Attachment Table Template .....	83
2.4.6.1.2	Message object Attachment Tables .....	83
2.4.6.1.3	Locating Attachment object Nodes from the Attachment Table .....	83
2.4.6.2	Attachment object PC.....	83
2.4.6.2.1	Property Schema of an Attachment object PC .....	83
2.4.6.3	Relationship between Attachment Table and Attachment objects .....	84
2.4.7	Named Property Lookup Map .....	84
2.4.7.1	NAMEID.....	85
2.4.7.2	The GUID Stream .....	85

2.4.7.3	The Entry Stream .....	86
2.4.7.4	The String Stream .....	86
2.4.7.5	Hash Table .....	86
2.4.7.6	Data Organization of the Name-to-ID-Map .....	86
2.4.8	Search .....	88
2.4.8.1	Search Update Descriptor (SUD).....	88
2.4.8.1.1	SUD Structure .....	88
2.4.8.2	SUDData Structures.....	90

# 1 Introduction

This document specifies the Outlook Personal Folders File Format, and provides the necessary technical information required to read and write the contents of a Personal Folders File (PST). This document also specifies the minimum requirements for a PST file to be recognizable as valid in order for implementers to create PST files that can be mounted and used by other implementations of the protocol.

## 1.1 Glossary

The following terms are defined in [\[MS-GLOS\]](#):

**cyclic redundancy check (CRC)**  
**object**  
**property set**

The following terms are defined in [\[MS-OFCGLOS\]](#):

**property identifier**

The following terms are specific to this document:

**Attachment object:** A set of properties that represents a file, Message object, or structured storage that is attached to a Message object and is visible through the attachment table for a Message object.

**FAI contents table:** A table of folder associated information (FAI) Message objects that are stored in a Folder object.

**Folder associated information (FAI):** A collection of Message objects that are stored in a Folder object and are typically hidden from view by e-mail applications. An FAI Message object is used to store a variety of settings and auxiliary data, including forms, views, calendar options, favorites, and category lists.

**Folder object:** A messaging construct that is typically used to organize data into a hierarchy of objects containing Message objects and folder associated information (FAI) Message objects.

**Message object:** A set of properties that represents an e-mail message, appointment, contact, or other type of personal-information-management object. In addition to its own properties, a Message object contains recipient properties that represent the addressees to which it is addressed, and an attachment table that represents any files and other Message objects that are attached to it.

**Message store:** A unit of containment for a hierarchy of Folder objects, such as a mailbox.

**named property:** A property that is identified by both a GUID and either a string name or a 32-bit identifier, such as a language identifier (LID) or IDispatch identifier (DispID).

**property tag:** A 32-bit value that contains a property type and a property identifier. The low-order 16 bits represent the property type. The high-order 16 bits represent the property identifier.

**property type:** A 16-bit quantity that specifies the data type of a property value.

**spam:** An unsolicited e-mail message.

**MAY, SHOULD, MUST, SHOULD NOT, MUST NOT:** These terms (in all caps) are used as described in [\[RFC2119\]](#). All statements of optional behavior use either MAY, SHOULD, or SHOULD NOT.

## 1.3 Structure Overview

The Outlook Personal Folders File Format (PST file format) is a stand-alone, self-contained, structured binary file format that does not require any external dependencies. Each PST file represents a **Message store** that contains an arbitrary hierarchy of **Folder objects**, which contains

**Message objects**, which can contain **Attachment objects**. Information about Folder objects, Message objects, and Attachment objects are stored in properties, which collectively contain all of the information about the particular item.

### 1.3.1 Logical Architecture of a PST File

The PST file structures are logically arranged in three layers: the NDB (Node Database) Layer, the LTP (Lists, Tables, and Properties) Layer, and the Messaging Layer. The following diagram illustrates the logical hierarchy of these layers, and what abstractions are handled by each layer.

**Figure 1: Logical Layers of a PST File**

#### 1.3.1.1 The Node Database (NDB) Layer

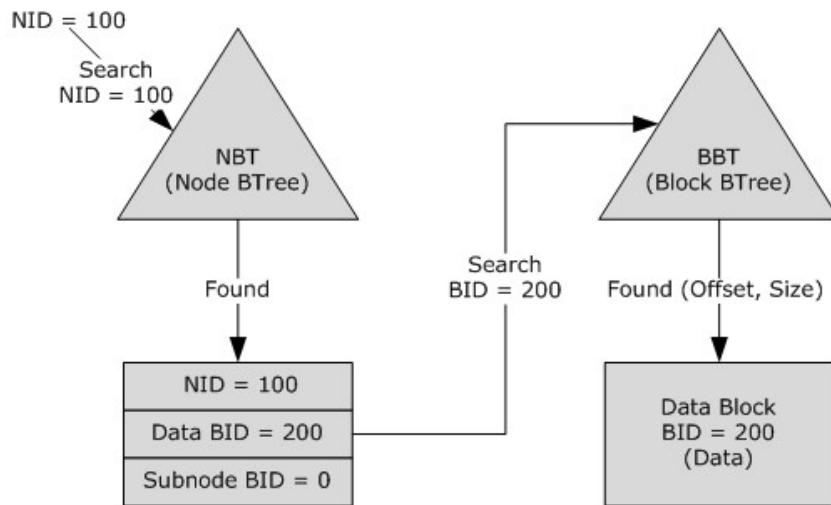

The NDB Layer consists of a database of nodes, which represents the lower-level storage facilities of the PST file format. From an implementation standpoint, the NDB Layer consists of the header, file allocation information, blocks, nodes, and two BTrees: the Node BTTree (NBT) and the Block BTTree (BBT).

The NBT contains references to all of the accessible nodes in the PST file. Its BTTree implementation allows for efficient searches to locate any specific node. Each node reference is represented using a set of four properties that includes its NID, parent NID, data BID, and subnode BID. The data BID points to the block that contains the data associated with the node, and the subnode BID points to the block that contains references to subnodes of this node. Top-level NIDs are unique across the PST and are searchable from the NBT. Subnode NIDs are only unique within a node and are not searchable (or found) from the NBT. The parent NID is an optimization for the higher layers and has no meaning for the NDB Layer.

The BBT contains references to all of the data blocks of the PST file. Its BTTree implementation allows for efficient searches to locate any specific block. A block reference is represented using a set of four properties, which includes its BID, IB, CB, and CREF. The IB is the offset within the file where the block is located. The CB is the count of bytes stored within the block. The CREF is the count of references to the data stored within the block.

The roots of the NBT and BBT can be accessed from the header of the PST file.

The following diagram illustrates the high-level relationship between nodes and blocks.

**Figure 2: Relationship between nodes and blocks**

The preceding figure illustrates how the data of a node with NID=100 can be accessed. The NBT is searched to find the record with NID=100. Once found, the record contains the BID (200) of the block that contains the node's data. With the BID, the BBT can be searched to locate the block that contains the node's data. As shown in the diagram, it is always necessary to search both the NBT and BBT to locate the data for a top-level node.

### 1.3.1.2 The Lists, Tables, and Properties (LTP) Layer

The LTP Layer implements higher-level concepts on top of the NDB construct. The core elements of the LTP Layer are the Property Context (PC) and Table Context (TC). A PC represents a collection of properties. A TC represents a two-dimensional table. The rows represent a collection of properties. The columns represent which properties are within the rows.

From a high-level implementation standpoint, each PC or TC is stored as data in a single node. The LTP Layer uses NIDs to identify PCs and TCs.

To implement PCs and TCs efficiently, the LTP Layer employs the following two types of data structures on top of each NDB node.

#### 1.3.1.2.1 Heap-on-Node (HN)

A Heap-on-Node is a heap data structure that is implemented on top of a node. The HN enables sub-allocating the data stream of a node into small, variable-sized fragments . The prime example of HN usage is to store various string values into a single block. More complex data structures are built on top of the HN.

#### 1.3.1.2.2 BTree-on-Heap (BTH)

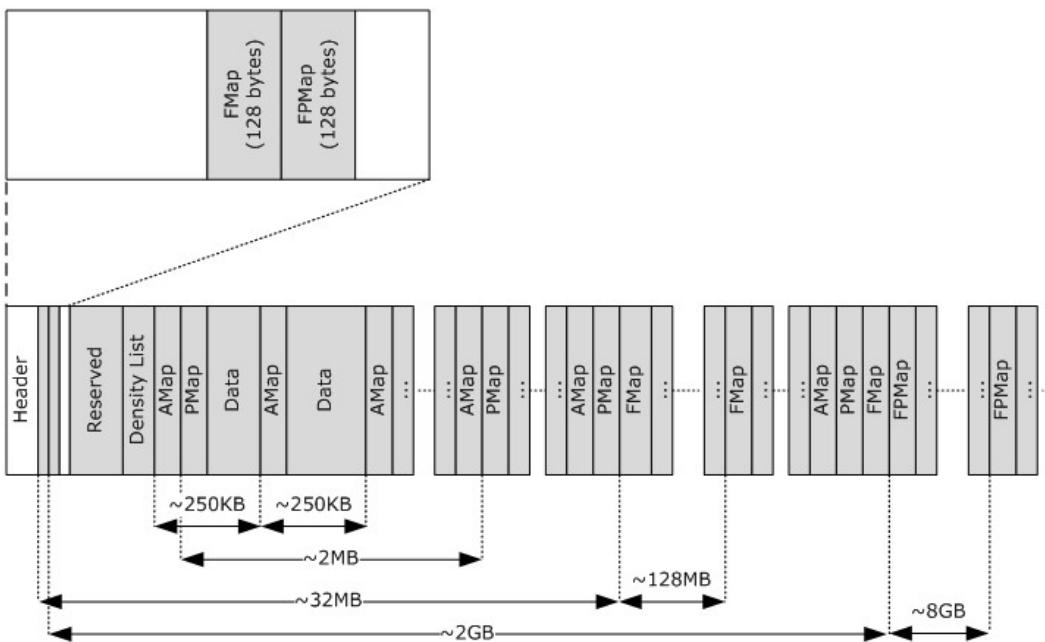

A BTree-on-Heap data structure is implemented by building inside of a HN structure. The HN provides a quick way to access the BTree structures, whereas the BTH provides an expedient way to search through data. PCs are implemented as BTHs.

### 1.3.1.3 The Messaging Layer

The Messaging Layer consists of the higher-level rules and business logic that allow the structures of the LTP and NDB Layers to be combined and interpreted as Folder objects, Message objects, Attachment objects, and properties. The Messaging Layer also defines the rules and requirements that need to be followed when modifying the contents of a PST file so that the modified PST file can still be successfully read by implementations of this protocol.

## 1.3.2 Physical Organization of the PST File Format

This section provides an overview of the physical layout of the various concepts that were introduced in section 1.3.1. The following diagram illustrates the high-level file organization of a PST.

**Figure 3: Physical Organization of the PST File Format**

The PST file format is organized with a header element followed by allocation information pages at regular intervals that are interspersed with extensible data blocks. The header section includes metadata about the PST and information that points to the data sections that contain the Message store and its contents. The following sections cover each of these elements in further detail.

### 1.3.2.1 Header

The header resides at the very beginning of the file, and contains three main groups of information: Metadata, root record, and initial free map (FMap) and free page map (FPMap). For more information about the HEADER structure, see section [2.2.2.6](#).

#### 1.3.2.1.1 Metadata and State of the PST File

The metadata includes information such as version numbers, checksums, persistent counters, and namespace tables. Using this information, an implementation can determine the version and format of the PST file, which determines the layout of the subsequent data in the file.

### **1.3.2.1.2 Root Record**

The root record contains information about the actual data that is stored in the PST file. This includes the root of the NBT and BBT, size and allocation information required to manage the free space and file growth, as well as file integrity information. For more information about the ROOT structure, see section [2.2.2.5](#).

### **1.3.2.1.3 Initial Free Map (FMap) and Free Page Map (FPMMap)**

Free Maps (FMaps) and Free Page Maps (FPMMaps) are used to search for contiguous free space within a PST file. <[1](#)> FMaps and FPMMaps are further described in greater detail in sections section [1.3.2.7](#) and section [1.3.2.8](#).

### **1.3.2.2 Reserved Data**

A number of octets have been reserved between the end of the HEADER and the beginning of the Density List (DList). Part of this space is reserved for future expansion of the PST file HEADER structure, while the rest is reserved for persisting transient, implementation-specific data.

### **1.3.2.3 Density List (DList)**

The Density List consists of an ordered list of references to Allocation Map (AMap) pages (see section [1.3.2.4](#)). It is sorted in order of ascending density (that is, by descending amount of free space available). Its function is to optimize the space allocation so that space referred to by pages with the most abundant free space (that is, lowest density) is allocated first. There is only one DList in the PST, which is always located at a fixed offset in the PST file. For more details about the technical details of the DList, see section [2.2.2.7.4](#). <[2](#)>

### **1.3.2.4 Allocation Map (AMap)**

An Allocation Map page is a fixed-size page that is used to track the allocation status of the data section that immediately follows the AMap page in the file. The entire AMap page can be viewed as an array of bits, where each bit corresponds to the allocation state of 64 bytes of data. An AMap page appears roughly every 250KB in the PST (see the diagram in section [1.3.2](#)). For more details about the AMap, see section [2.2.2.7.2](#).

### **1.3.2.5 Page Map (PMap)**

A Page Map is a block of data that is 512 bytes in size (including overhead), which is used for storing almost all of the metadata in the PST (that is, the BBT and NBT). The PMap is created to optimize for the search of available pages. The PMap is almost identical to the AMap, except that each bit in the PMap maps the allocation state of 512 bytes rather than instead of 64 because each bit in the PMap covers eight times the data of an AMap, a PMap page appears roughly every 2MB (or one PMap for every eight AMaps). For more details about the PMap, see section [2.2.2.7.3](#).

### **1.3.2.6 Data Section**

Data sections are groups of data roughly 250KB in size that contain allocations. Each individual allocation is aligned to a 64-byte boundary, and is in sizes that are multiples of 64 bytes. All of the blocks referred to by the BBT are allocated out of these data sections. Data sections are represented by the blocks labeled "Data" in the diagram in section [1.3.1](#).

### **1.3.2.7 Free Map (FMap)**

An FMap page provides a mechanism to quickly locate contiguous free space. Each byte in the FMap corresponds to one AMap page. The value of each byte indicates the longest number of free bits found in the corresponding AMap page. Because each bit in the AMap maps to 64 bytes, the FMap contains the maximum amount of contiguous free space in that AMap, up to about 16KB. Generally, because each AMap covers about 250KB of data, each FMap page (496 bytes) covers around 125MB of data.

However, a special case exists for the initial FMap. As shown in the diagram in section [1.3.1](#), the HEADER contains an initial FMap, which is only 128 bytes, and which covers the first 32MB of data.

### **1.3.2.8 Free Page Maps (FPMap)**

An FPMap is similar to the FMap except that it is used to quickly find free pages. Each bit in the FPMap corresponds to a PMap page, and the value of the bit indicates whether there are any free pages within that PMap page. With each PMap covering about 2MB, and an FPMap page at 496 bytes, it follows that an FPMap page covers about 8GB of space.

However, a special case exists for the initial FPMap. As shown in the diagram in section 1.3.1, the HEADER contains an initial FPMap, which is only 128 bytes, which covers the first 2GB of data.

ANSI PSTfiles only contain the initial FPMap in the HEADER and no additional FPMap pages. This limits the size of an ANSI PST file to about 2GB.

## **1.4 Relationship to Protocols and Other Structures**

The Outlook Personal Folders File Format uses structures specified in [\[MS-OXCDATA\]](#) and property tags specified in [\[MS-OXPROPS\]](#).

## **1.5 Applicability Statement**

This protocol allows implementers to read and write PST files that are compatible with other implementations of this protocol.

## **1.6 Versioning and Localization**

None.

## **1.7 Vendor-Extensible Fields**

None.

## 2 Structures

This section provides detailed technical information about all of the data structures that are used in the PST file format, as applicable to the scope of this document.

### 2.1 Property and Data Type Definitions

#### 2.1.1 Data Types

The following data types are specified in [\[MS-DTYP\]](#):

**bit**  
**byte**  
**DWORD**  
**GUID**  
**ULONG**  
**ULONGLONG**  
**WORD**

The following data types are specified in [\[MS-OXCDATA\]](#) section 2.12.1:

**PtypBinary**  
**PtypBoolean**  
**PtypGuid**  
**PtypInteger32**  
**PtypInteger64**  
**PtypMultipleInteger32**  
**PtypObject**  
**PtypString**  
**PtypString8**  
**PtypTime**

This specification uses the following notations to indicate data size.

Notation	Meaning	Value
KB	kilobyte	1024 bytes
MB	megabyte	1024 kilobytes
GB	gigabyte	1024 megabytes

#### 2.1.2 Properties

This protocol defines the following **property tags**. The **PropertyTag** structure is specified in [\[MS-OXCDATA\]](#) section 2.10.

Canonical Name	PropertyTag.PropertyId	PropertyTag.PropertyType
<b>PidTagNameidBucketCount</b>	0x0001	<b>PtypInteger32</b>
<b>PidTagNameidStreamGuid</b>	0x0002	<b>PtypBinary</b>
<b>PidTagNameidStreamEntry</b>	0x0003	<b>PtypBinary</b>
<b>PidTagNameidStreamString</b>	0x0004	<b>PtypBinary</b>
<b>PidTagNameidBucketBase</b>	0x1000	<b>PtypBinary</b>
<b>PidTagItemTemporaryFlags</b>	0x1097	<b>PtypInteger32</b>
<b>PidTagPstBodyPrefix</b>	0x6619	<b>PtypString</b>
<b>PidTagPstBestBodyProptag</b>	0x661D	<b>PtypInteger32</b>
<b>PidTagPstLrNoRestrictions</b>	0x6633	<b>PtypBoolean</b>
<b>PidTagPstHiddenCount</b>	0x6635	<b>PtypInteger32</b>
<b>PidTagPstHiddenUnread</b>	0x6636	<b>PtypInteger32</b>
<b>PidTagLatestPstEnsure</b>	0x66FA	<b>PtypInteger32</b>
<b>PidTagPstIpmsuBTreeDescendant</b>	0x6705	<b>PtypBoolean</b>
<b>PidTagPstSuBTreeContainer</b>	0x6772	<b>PtypInteger32</b>
<b>PidTagLtpParentNid</b>	0x67F1	<b>PtypInteger32</b>
<b>PidTagLtpRowId</b>	0x67F2	<b>PtypInteger32</b>
<b>PidTagLtpRowVer</b>	0x67F3	<b>PtypInteger32</b>
<b>PidTagPstPassword</b>	0x67FF	<b>PtypInteger32</b>
<b>PidTagMapiFormComposeCommand</b>	0x682F	<b>PtypString</b>

## 2.2 NDB Layer

The following sections describe the data structures used in the NDB Layer of the PST file.

### 2.2.1 Fundamental Concepts

The NDB Layer provides the abstractions to:

- Divide the PST file into logical streams.
- Establish hierarchical relationships between the streams.
- Provide transaction functionality when modifying data within the streams.

#### 2.2.1.1 Nodes

The NDB Layer uses the concept of "nodes" to divide the data in the PST file into logical streams. A node is an abstraction that consists of a stream of bytes and a collection of subnodes. It is implemented by the NDB Layer as a data block (section [2.2.2.8.3.1](#)) and a subnode BTee (section

[2.2.2.8.3.3](#)). The NBTENTRY structures in the Node BTree (section [2.2.2.7.7.4](#)) exist to define which blocks combine to form nodes.

## 2.2.1.2 ANSI Versus Unicode

There are currently 2 versions of the PST file format: ANSI and Unicode. The ANSI PST file format is the legacy format and SHOULD NOT be used to create new PST files. The Unicode PST file format is the currently-used format. [<3>](#)

While the nomenclature suggests a difference in how the internal strings are represented in the PST file, there are other significant differences between the ANSI and Unicode PST file formats. The most significant difference is the sizes of various core data elements that are used throughout the NDB Layer. Specifically, the ANSI version uses 32-bit values to represent block IDs (BIDs) and absolute file offsets (IB). The Unicode version uses 64-bit values instead. Some other values that were represented using 32-bits have also been extended to use 64-bits. Those cases are discussed on a case-by-case basis.

Because BIDs and IBs are used extensively throughout the NDB Layer, the version-specific size differences affect most of the NDB data structures. ANSI and Unicode versions of the data structures are defined separately whenever there are material differences between the two versions.

## 2.2.2 Data Structures

### 2.2.2.1 NID (Node ID)

Nodes provide the primary abstraction used to reference data stored in the PST file that is not interpreted by the NDB Layer. Each node is identified using its NID. Each NID is unique within the namespace in which it is used. Each node referenced by the NBT MUST have a unique NID. However, two subnodes of two different nodes can have identical NIDs, but two subnodes of the same node MUST have different NIDs.

Unicode / ANSI:

0	1	2	3	4	5	6	7	8	9	1	0	1	2	3	4	5	6	7	8	9	2	0	1	2	3	4	5	6	7	8	9	3	0	1
<b>nidType</b>		<b>nidIndex</b>																																

**nidType (5 bits):** Identifies the type of the node represented by the NID. The following table specifies a list of values for **nidType**. However, it is worth noting that **nidType** has no meaning to the structures defined in the NDB Layer.

Value	Friendly Name	Description
0x00	NID_TYPE_HID	Heap node
0x01	NID_TYPE_INTERNAL	Internal node (section <a href="#">2.4.1</a> )
0x02	NID_TYPE_NORMAL_FOLDER	Normal Folder object (PC)
0x03	NID_TYPE_SEARCH_FOLDER	Search Folder object (PC)
0x04	NID_TYPE_NORMAL_MESSAGE	Normal Message object (PC)

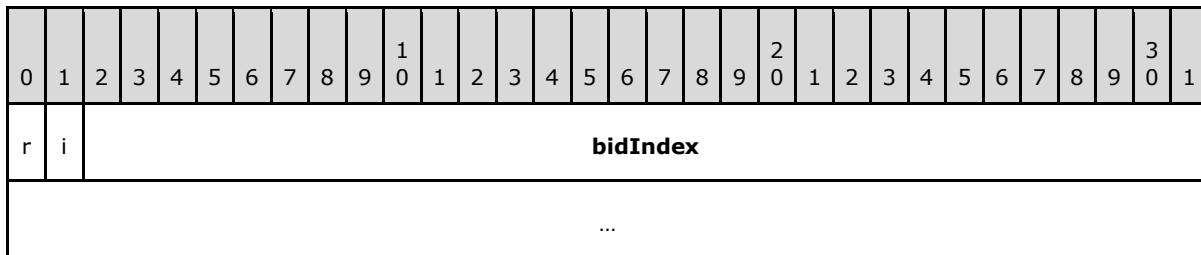

Value	Friendly Name	Description
0x05	NID_TYPE_ATTACHMENT	Attachment object (PC)
0x06	NID_TYPE_SEARCH_UPDATE_QUEUE	Queue of changed objects for search Folder objects
0x07	NID_TYPE_SEARCH_CRITERIA_OBJECT	Defines the search criteria for a search Folder object
0x08	NID_TYPE_ASSOC_MESSAGE	<b>Folder associated information (FAI) Message object (PC)</b>
0x0A	NID_TYPE_CONTENTS_TABLE_INDEX	Internal, persisted view-related
0x0B	NID_TYPE_RECEIVE_FOLDER_TABLE	Receive Folder object (Inbox)
0x0C	NID_TYPE_OUTGOING_QUEUE_TABLE	Outbound queue (Outbox)
0x0D	NID_TYPE_HIERARCHY_TABLE	Hierarchy table (TC)
0x0E	NID_TYPE_CONTENTS_TABLE	Contents table (TC)
0x0F	NID_TYPE_ASSOC_CONTENTS_TABLE	<b>FAI contents table (TC)</b>
0x10	NID_TYPE_SEARCH_CONTENTS_TABLE	Contents table (TC) of a search Folder object
0x11	NID_TYPE_ATTACHMENT_TABLE	Attachment table (TC)
0x12	NID_TYPE_RECIPIENT_TABLE	Recipient table (TC)
0x13	NID_TYPE_SEARCH_TABLE_INDEX	Internal, persisted view-related
0x1F	NID_TYPE_LTP	LTP

**nidIndex (27 bits):** The identification portion of the NID.

### 2.2.2.2 BID (Block ID)

Each block is uniquely identified in the PST file using its BID value. The indexes of BIDs are assigned in a monotonically increasing fashion so that it is possible to establish the order in which blocks were created by examining the BIDs.

Unicode:

ANSI:

0	1	2	3	4	5	6	7	8	9	1	0	1	2	3	4	5	6	7	8	9	2	0	1	2	3	4	5	6	7	8	9	3	0	1
r	i	<b>bidIndex</b>																																

**r (1 bit):** Reserved bit. Readers MUST ignore this bit and treat it as zero (0) before looking up the BID from the BBT. Writers MUST set this bit to zero (0).

**i (1 bit):** MUST set to "1" when the block is "Internal", or "0" when the block is not "Internal". An internal block is an intermediate block that, instead of containing actual data, contains metadata about how to locate other data blocks that contain the desired information. For more details about technical details regarding blocks, see section [2.2.2.8](#).

**bidIndex (Unicode: 62 bits; ANSI: 30 bits):** A monotonically increasing value that uniquely identifies the BID within the PST file. **bidIndex** values are assigned based on the **bidNextB** value in the HEADER structure (see section 2.1.2.3). The **bidIndex** increments by one each time a new BID is assigned.

### 2.2.2.3 IB (Byte Index)

The IB (Byte Index) is used to represent an absolute offset within the PST file with respect to the beginning of the file. The IB is a simple unsigned integer value and is 64 bits in Unicode versions and 32 bits in ANSI versions.

### 2.2.2.4 BREF

The **BREF** is a record that maps a BID to its absolute file offset location.

Unicode:

0	1	2	3	4	5	6	7	8	9	1	0	1	2	3	4	5	6	7	8	9	2	0	1	2	3	4	5	6	7	8	9	3	0	1
bid																																		
...																																		
ib																																		
...																																		

ANSI:

0	1	2	3	4	5	6	7	8	9	1	0	1	2	3	4	5	6	7	8	9	2	0	1	2	3	4	5	6	7	8	9	3	0	1
bid																																		

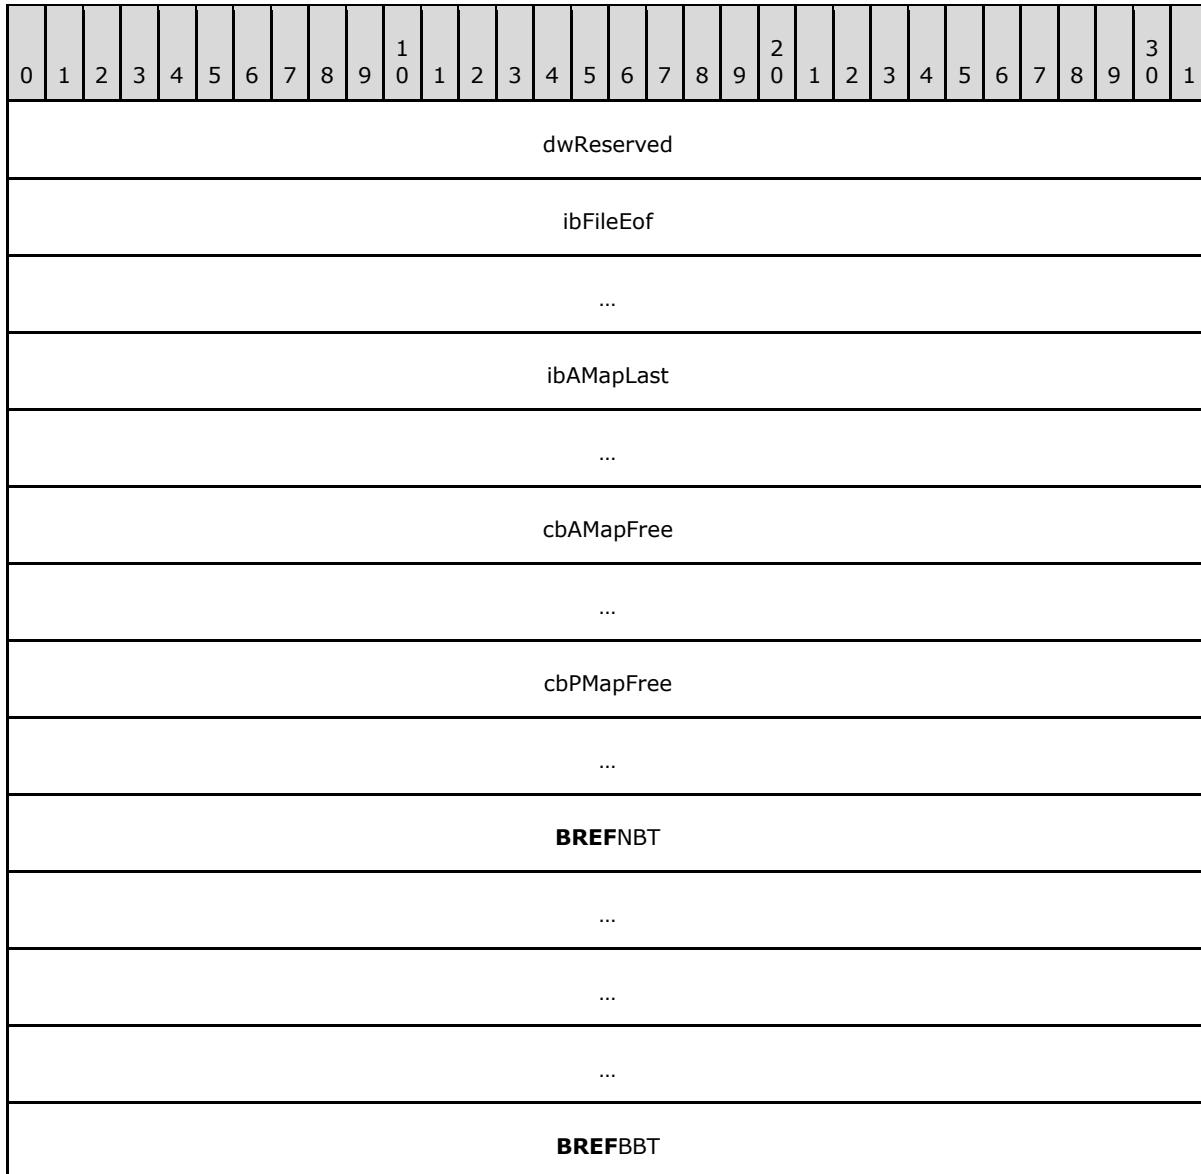

**bid (Unicode: 64 bits; ANSI: 32 bits):** A BID structure, as specified in section [2.2.2.2](#).

**ib (Unicode: 64 bits; ANSI: 32 bits):** An IB structure, as specified in section [2.2.2.3](#).

## 2.2.2.5 ROOT

The ROOT structure contains current file state.

Unicode:

		...
		...
		...
fAMapValid	bReserved	wReserved

ANSI:

0	1	2	3	4	5	6	7	8	9	1	0	1	2	3	4	5	6	7	8	9	2	0	1	2	3	4	5	6	7	8	9	3	0	1
dwReserved																																		
ibFileEof																																		
ibAMapLast																																		
cbAMapFree																																		
cbPMapFree																																		
<b>BREFNBT</b>																																		
...																																		
<b>BREFBBT</b>																																		
...																																		
fAMapValid	bReserved	wReserved																																

**dwReserved (4 bytes):** Implementations SHOULD ignore this value and SHOULD NOT modify it. Creators of a new PST file MUST initialize this value to zero (0). <[4](#)>

**ibFileEof (Unicode: 8 bytes; ANSI 4 bytes):** The size of the PST file, in bytes.

**ibAMapLast (Unicode: 8 bytes; ANSI 4 bytes):** An IB structure (section [2.2.2.3](#)) that contains the absolute file offset to the last AMap page of the PST file.

**cbAMapFree (Unicode: 8 bytes; ANSI 4 bytes):** The total free space in all AMaps, combined.

**cbPMapFree (Unicode: 8 bytes; ANSI 4 bytes):** The total free space in all PMaps, combined. Because the PMap is deprecated, this value SHOULD be zero (0). Creators of new PST files MUST initialize this value to zero (0).

**BREFNBT (Unicode: 16 bytes; ANSI: 8 bytes):** A **BREF** structure (section [2.2.2.4](#)) that references the root page of the Node BTTree (NBT).

**BREFBBT (Unicode: 16 bytes; ANSI: 8 bytes):** A **BREF** structure that references the root page of the Block BTTree (BBT).

**fAMapValid (1 byte):** Indicates whether all of the AMaps in this PST file are valid. For more details, see section [2.6.1.3.8](#). This value MUST be set to one of the pre-defined values specified in the following table.

Value	Friendly Name	Meaning
0x00	INVALID_AMAP	One or more AMaps in the PST are INVALID
0x01	VALID_AMAP1	Deprecated. Implementations SHOULD NOT use this value. The AMaps are VALID. < <a href="#">5</a> >
0x02	VALID_AMAP2	The AMaps are VALID.

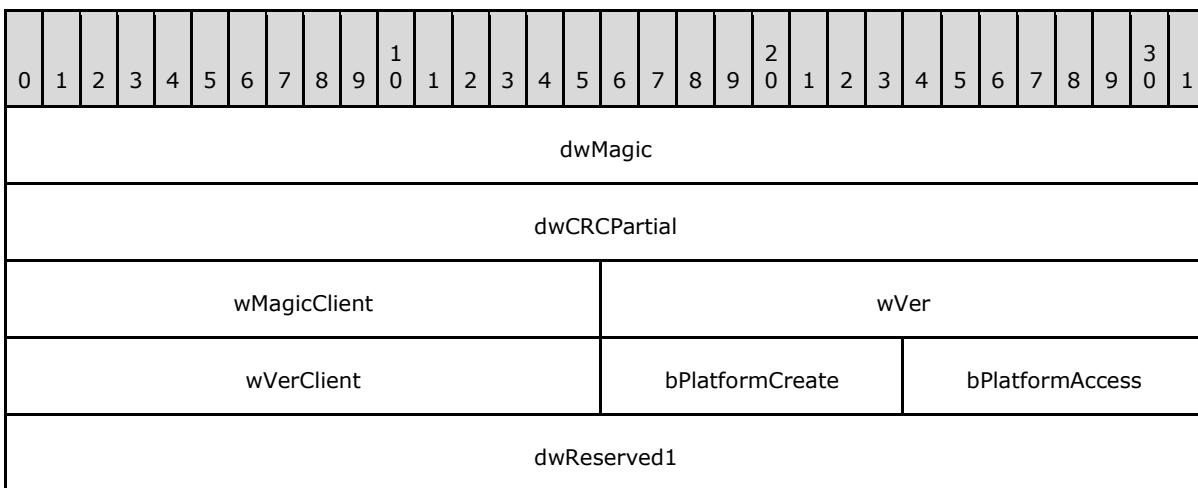

**bReserved (1 byte):** Implementations SHOULD ignore this value and SHOULD NOT modify it. Creators of a new PST file MUST initialize this value to zero (0). <[6](#)>

**wReserved (2 bytes):** Implementations SHOULD ignore this value and SHOULD NOT modify it. Creators of a new PST file MUST initialize this value to zero (0). <[7](#)>

## 2.2.2.6 HEADER

The HEADER structure is located at the beginning of the PST file (absolute file offset 0), and contains metadata about the PST file, as well as the ROOT information to access the NDB Layer data structures.

Unicode:

dwReserved2

rgbFP (128 bytes)																																																													
bSentinel										bCryptMethod				rgbReserved																																															
ullReserved																																																													
...																																																													
dwReserved																																																													
rgbReserved2																											bReserved																																		
rgbReserved3 (32 bytes)																																																													

**dwMagic (4 bytes):** MUST be { 0x21, 0x42, 0x44, 0x4E } ("!BDN").

**dwCRCPartial (4 bytes):** The 32-bit **cyclic redundancy check (CRC)** value of the 471 bytes of data starting from **wMagicClient** (Offset 0x0008)

**wMagicClient (2 bytes):** MUST be { 0x53, 0x4D }.

**wVer (2 bytes):** File format version. This value MUST be 15 if the file is an ANSI PST file, and MUST be 23 if the file is a Unicode PST file.

**wVerClient (2 bytes):** Client file format version. The version that corresponds to the format described in this document is 19. Creators of a new PST file based on this document SHOULD initialize this value to 19.

**bPlatformCreate (1 byte):** This value MUST be set to 0x01.

**bPlatformAccess (1 byte):** This value MUST be set to 0x01.

**dwReserved1 (4 bytes):** Implementations SHOULD ignore this value and SHOULD NOT modify it. Creators of a new PST file MUST initialize this value to zero (0). <[<8>](#)>

**dwReserved2 (4 bytes):** Implementations SHOULD ignore this value and SHOULD NOT modify it. Creators of a new PST file MUST initialize this value to zero (0). <[<9>](#)>

**bidUnused (8 bytes):** Unused padding added when the Unicode PST file format was created.

**bidNextP (Unicode: 8 bytes; ANSI: 4 bytes):** Next page BID. Pages have a special counter for allocating **bidIndex** values. The value of **bidIndex** for BIDs for pages is allocated from this counter.

**bidNextB (Unicode: 8 bytes; ANSI: 4 bytes):** Next BID. This value is the monotonic counter that indicates the BID to be assigned for the next allocated block. BID values advance in increments of 4. For more details, see section [2.2.2.2](#).

**dwUnique (4 bytes):** This is a monotonically-increasing value that is modified every time the PST file's HEADER structure is modified. The function of this value is to provide a unique value, and to ensure that the HEADER CRCs are different after each header modification.

**rgnid[] (128 bytes):** A fixed array of 32 NIDs, each corresponding to one of the 32 possible NID\_TYPES (section [2.2.2.1](#)). Different NID\_TYPES can have different starting **nidIndex** values. When a blank PST file is created, these values are initialized by NID\_TYPE according to the following table. Each of these NIDs indicates the last **nidIndex** value that had been allocated for the corresponding NID\_TYPE. When a NID of a particular type is assigned, the corresponding slot in **rgnind** is also incremented by one (1):

NID_TYPE	Starting nidIndex
NID_TYPE_NORMAL_FOLDER	1024 (0x400)
NID_TYPE_SEARCH_FOLDER	16384 (0x4000)
NID_TYPE_NORMAL_MESSAGE	65536 (0x10000)
NID_TYPE_ASSOC_MESSAGE	32768 (0x8000)
Any other NID_TYPE	1024 (0x400)

**qwUnused (8 bytes):** Unused space; MUST be set to zero (0). Unicode PST file format only.

**root (Unicode: 72 bytes; ANSI: 40 bytes):** A ROOT structure (section [2.2.2.5](#)).

**dwAlign (4 bytes):** Unused alignment bytes; MUST be set to zero (0). Unicode PST file format only.

**rgbFM (128 bytes):** Deprecated FMap. This is no longer used and MUST be filled with 0xFF. Readers SHOULD ignore the value of these bytes.

**rgbFP (128 bytes):** Deprecated FPMAP. This is no longer used and MUST be filled with 0xFF. Readers SHOULD ignore the value of these bytes.

**bSentinel (1 byte):** MUST be set to 0x80.

**bCryptMethod (1 byte):** Indicates how the data within the PST file is encoded. MUST be set to one of the following pre-defined values:

Value	Friendly Name	Meaning
0x00	NDB_CRYPT_NONE	Data blocks are not encoded
0x01	NDB_CRYPT_PERMUTE	Encoded with Permutation Algorithm (section <a href="#">5.1</a> )
0x02	NDB_CRYPT_CYCLIC	Encoded with Cyclic Algorithm (section <a href="#">5.2</a> )

**rgbReserved (2 bytes):** Reserved; MUST be set to zero (0).

**bidNextB (8 bytes):** Indicates the next available BID value. Unicode PST file format only.

**dwCRCFull (4 bytes):** The 32-bit CRC value of the 516 bytes of data starting from **wMagicClient** to **bidNextB**, inclusive. Unicode PST file format only.

**ullReserved (8 bytes):** Reserved; MUST be set to zero (0). ANSI PST file format only.

**dwReserved (4 bytes):** Reserved; MUST be set to zero (0). ANSI PST file format only.

**rgbReserved2 (3 bytes):** Implementations SHOULD ignore this value and SHOULD NOT modify it. Creators of a new PST MUST initialize this value to zero (0). <[10](#)>>

**bReserved (1 byte):** Implementations SHOULD ignore this value and SHOULD NOT modify it. Creators of a new PST file MUST initialize this value to zero (0). <[11](#)>>

**rgbReserved3 (32 bytes):** Implementations SHOULD ignore this value and SHOULD NOT modify it. Creators of a new PST MUST initialize this value to zero (0). <[12](#)>>

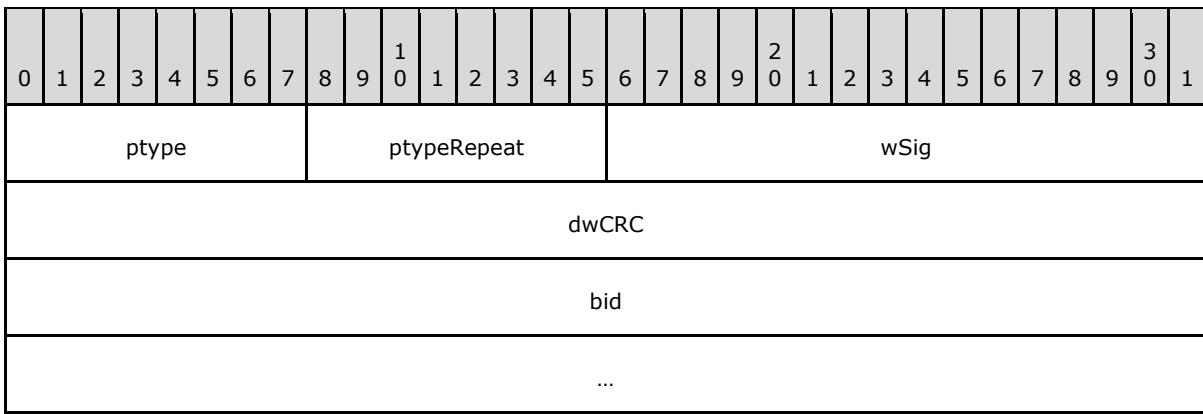

## 2.2.2.7 Pages

A page is a fixed-size structure of 512 bytes that is used in the NDB Layer to represent allocation metadata and BTREE data structures. A page trailer is placed at the very end of every page such that the end of the page trailer is aligned with the end of the page.

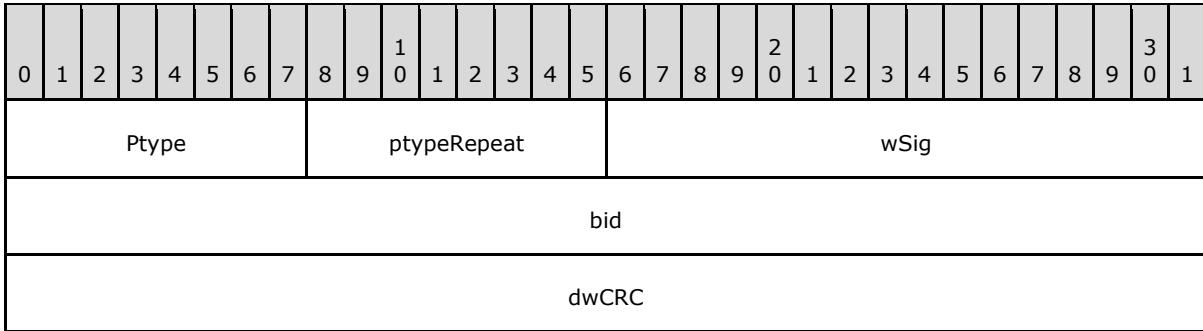

### 2.2.2.7.1 PAGETRAILER

A PAGETRAILER structure contains information about the page in which it is contained. PAGETRAILER structure is present at the very end of each page in a PST file.

Unicode:

ANSI:

**ptype (1 byte):** This value indicates the type of data contained within the page. This field MUST contain one of the following values.

Value	Friendly Name	Meaning	wSig Value
0x80	ptypeBBT	Block BTree page	block / page Signature (section <a href="#">5.5</a> )
0x81	ptypeNBT	Node BTree page	block / page Signature (section <a href="#">5.5</a> )
0x82	ptypeFMap	Free Map page	0x0000
0x83	ptypePMap	Allocation Page Map page	0x0000
0x84	ptypeAMap	Allocation Map page	0x0000
0x85	ptypeFPMAP	Free Page Map page	0x0000
0x86	ptypeDL	Density List page	block / page Signature (section <a href="#">5.5</a> )

**ptypeRepeat (1 byte):** MUST be set to the same value as **ptype**.

**wSig (2 bytes):** Page signature. This value depends on the value of the **ptype** field. This value is zero (0x0000) for AMap, PMap, FMap, and FPMAP pages. For BBT, NBT, and DList pages, a page / block signature is computed (see section [5.5](#)).

**dwCRC (4 bytes):** 32-bit CRC of the page data, excluding the page trailer. See section [5.3](#) for the CRC algorithm.

**bid (Unicode: 8 bytes; ANSI 4 bytes):** The BID of the page's block. AMap, PMap, FMap, and FPMMap pages have a special convention where their BID is assigned the same value as their IB (that is, the absolute file offset of the page). The **bidIndex** for other page types are allocated from the special **bidNextP** counter in the HEADER structure.

### 2.2.2.7.2 AMap (Allocation Map) Page

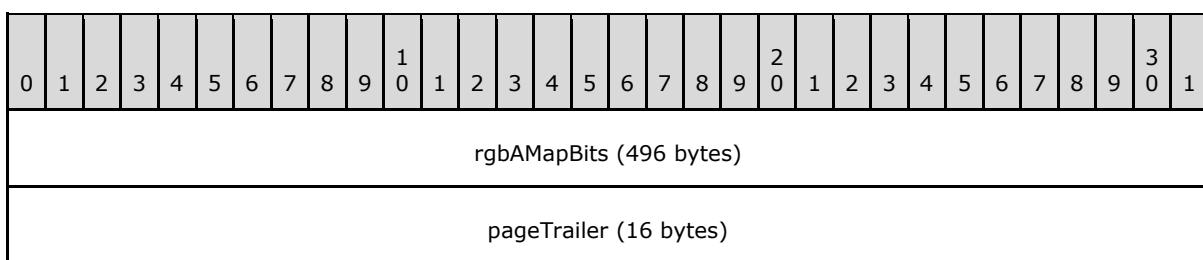

An AMap page contains an array of 496 bytes that is used to track the space allocation within the data section that immediately follows the AMap page. Each bit in the array maps to a block of 64 bytes in the data section. Specifically, the first bit maps to the first 64 bytes of the data section, the second bit maps to the next 64 bytes of data, and so on. AMap pages map a data section that consists of 253,952 bytes ( $496 * 8 * 64$ ).

An AMap is allocated out of the data section and, therefore, it actually "maps itself". What this means is that the AMap actually occupies the first page of the data section and the first byte (that is, 8 bits) of the AMap is always 0xFF, which indicates that the first 512 bytes are allocated for the AMap.

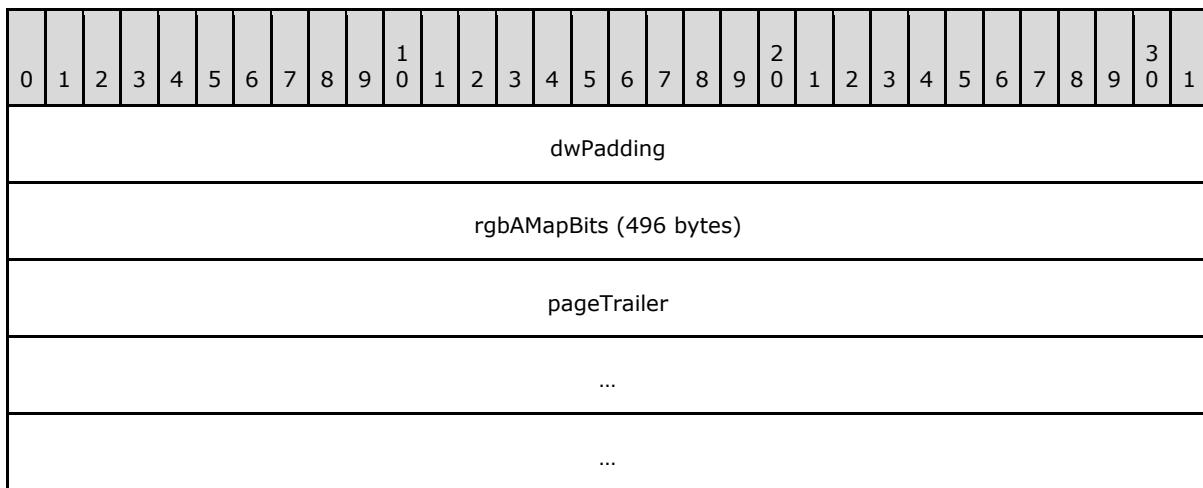

The first AMap of a PST file is always located at absolute file offset 0x4400, and subsequent AMaps appear at intervals of 253,952 bytes thereafter. The following is the structural representation of an AMap page.

#### 2.2.2.7.2.1 AMAPPAGE

Unicode:

ANSI:

**dwPadding (ANSI file format only, 4 bytes):** Unused padding; MUST be set to Zero (0).

**rgbAMapBits (496 bytes):** AMap data. This is represented as a sequence of bits that marks whether blocks of 64 bytes of data have been allocated. If the  $n^{\text{th}}$  bit is set to "1", then the  $n^{\text{th}}$  block of 64 bytes has been allocated. Alternatively, if the  $n^{\text{th}}$  bit is set to "0", then the  $n^{\text{th}}$  block of 64 bytes is not allocated (free).

**pageTrailer (Unicode: 16 bytes; ANSI: 12 bytes):** A **PAGETRAILER** structure (section [2.2.2.7.1](#)). The **ptype** subfield of **pageTrailer** MUST be set to **ptypeAMap**. The other subfields of **pageTrailer** MUST be set as specified in section [2.2.2.7.1](#).

### 2.2.2.7.3 PMap (Page Map) Page

A PMap is the same as an AMap, except that each bit in the PMap tracks 512-byte pages instead of blocks of 64 bytes. Because a page is equivalent to eight 64-byte blocks in size, one PMap appears for every eight AMaps. The purpose of the PMap is to optimize locating frequently-needed free pages for allocating metadata and BTree data structures. PMap pages, similar to AMap pages, are allocated from the data section whose allocation is also mapped in the corresponding AMap.

The PMap works by pre-allocating 4KB (eight pages) of memory from the AMap at a time. Once the memory is reserved from the AMap, the corresponding byte (eight pages equals 8 bits) in the PMap is zeroed out to indicate reserved pages. Implementations seeking to allocate a page search for bits set to "0" in the PMap to find free pages. The coverage of a PMap page is 2,031,616 bytes ( $496 * 8 * 512$ ) of data space.

The functionality of the PMap has been deprecated by the Density List. If a Density List is present in the PST file, then implementations SHOULD NOT use the PMap to locate free pages, and SHOULD instead use the Density List instead. <[13](#)> However, implementations MUST ensure the presence of PMaps at the correct intervals and maintain valid checksums to ensure backward-compatibility with older clients.

The first PMap of a PST file is always located at absolute file offset 0x4600. The following is the structural representation of a PMap page.

#### 2.2.2.7.3.1 PMAPPAGE

Unicode:

0	1	2	3	4	5	6	7	8	9	1	0	1	2	3	4	5	6	7	8	9	2	0	1	2	3	4	5	6	7	8	9	3	0	1
rgbPMapBits (496 bytes)																																		
pageTrailer (16 bytes)																																		

ANSI:

0	1	2	3	4	5	6	7	8	9	1	0	1	2	3	4	5	6	7	8	9	2	0	1	2	3	4	5	6	7	8	9	3	0	1
dwPadding																																		

rgbPMapBits (496 bytes)
pageTrailer
...
...

**dwPadding (ANSI file format only, 4 bytes):** Unused padding; MUST be set to Zero (0).

**rgbPMapBits (496 bytes):** PMap data. Each "0" bit corresponds to an available page that can be allocated. The meaning of "1" bits is ambiguous and SHOULD be ignored.

**pageTrailer (Unicode: 16 bytes; ANSI: 12 bytes):** A **PAGETRAILER** structure (section [2.2.2.7.1](#)). The **ptype** subfield of **pageTrailer** MUST be set to **ptypePMap**. The other subfields of **pageTrailer** MUST be set as specified in section [2.2.2.7.1](#).

#### 2.2.2.7.4 Density List (DList)

The Density List is a list of references to AMap pages that is sorted in order of ascending density (descending amount of free space available). Its purpose is to optimize the space allocation strategy where allocations are made from the pages with the most abundant free space first. The DList is an optional part of a PST file. However, implementations SHOULD create and use DLists.

There is at most one DList page in each PST file. If present, this page is always located at absolute file offset 0x4200. To maintain backward compatibility with older clients, the location of the DList is allocated out of the Reserved data area (section [1.3.2.2](#)) that is also used for transient storage. Because of the fact that this area is not dedicated exclusively for the DList, the DList can be overwritten at any time by other transient processes and, therefore, the DList is not guaranteed to be valid. If a DList page contains an invalid CRC, then its contents MUST NOT be used and SHOULD be recreated by using the information from all of the AMap pages in the PST file. Implementations SHOULD use the DList when a valid DList exists. <[14](#)>

##### 2.2.2.7.4.1 DLISTPAGEENT

Each DLISTPAGEENT record in the DList represents a reference to an AMap PAGE in the PST file.

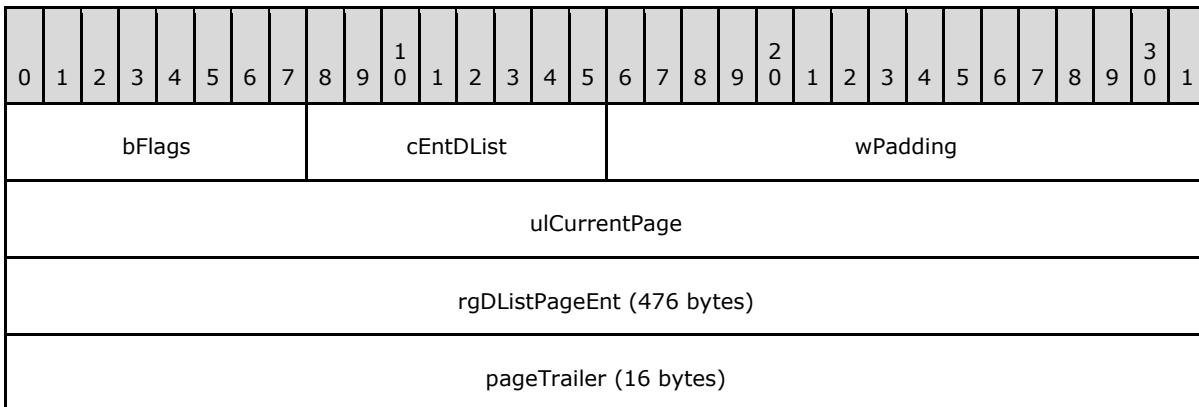

0	1	2	3	4	5	6	7	8	9	1	0	1	2	3	4	5	6	7	8	9	2	0	1	2	3	4	5	6	7	8	9	3	0	1
dwPageNum																dwFreeSlots																		

**dwPageNum (20 bits):** AMap page Number. This is the zero-based index to the AMap page that corresponds to this entry. A **dwPageNum** of "n" corresponds to the  $n^{\text{th}}$  AMap from the beginning of PST file.

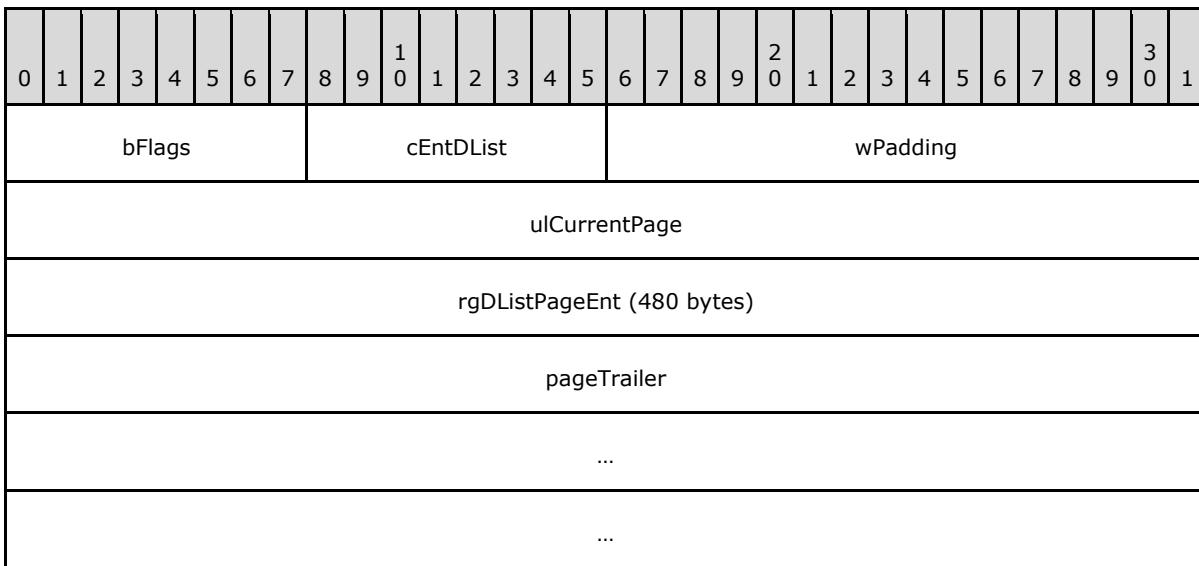

**dwFreeSlots (12 bits):** Total number of free slots in the AMap. This value is the aggregate sum of all free 64-byte slots in the AMap. Note that the free slots can be of any random configuration, and are not guaranteed to be contiguous.

## 2.2.2.7.4.2 DLISTPAGE

Unicode:

ANSI:

**bFlags (1 byte):** Flags; MUST be set to zero (0) or a combination of the following defined values.

Value	Friendly Name	Meaning
0x01	DFL_BACKFILL_COMPLETE	A DList backfill is not in progress

**cEntDList (1 byte):** Number of entries in the **rgDListPageEnt** array.

**wPadding (2 bytes):** Padding bytes; MUST be set to zero (0).

**ulCurrentPage (4 bytes):** The meaning of this field depends on the value of **bFlags**. If **DFL\_BACKFILL\_COMPLETE** is set in **bFlags**, then this value indicates the AMap page index that is used in the next allocation. If **DFL\_BACKFILL\_COMPLETE** is not set in **bFlags**, then this value

indicates the AMap page index that is attempted for backfilling in the next allocation. See section [2.6.1.3.4](#) for more information regarding Backfilling.

**rgDListPageEnt (Unicode: 476 bytes; ANSI: 480 bytes):** DList page entries. This is an array of DLISTPAGEENT records with **cEntDList** entries that constitute the DList. Each record contains an AMap page index and the aggregate amount of free slots available in that AMap. Note that, while the size of the field is fixed, the size of valid data within the field is not. Implementations MUST only read the number of DLISTPAGEENT entries from the array indicated by **cEntDList**.

**pageTrailer (Unicode: 16 bytes; ANSI: 12 bytes):** A **PAGETRAILER** structure (section [2.2.2.7.1](#)). The **ptype** subfield of **pageTrailer** MUST be set to **ptypeDL**. The other subfields of **pageTrailer** MUST be set as specified in section [2.2.2.7.1](#).

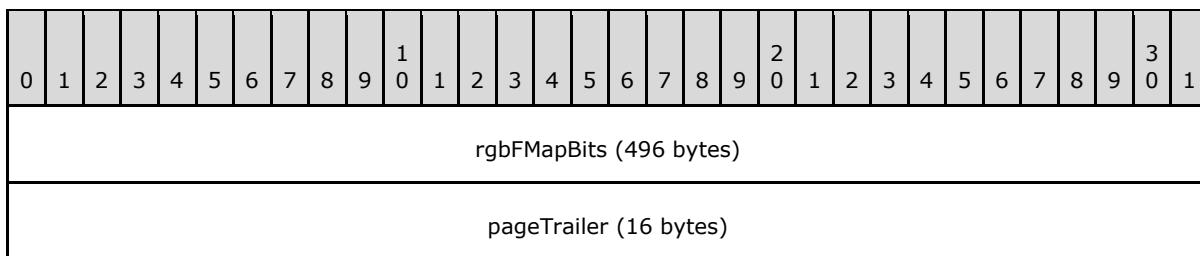

## 2.2.2.7.5 FMap (Free Map) Page

The general layout of an FMap is identical to that of an AMap, except that each byte in the FMap corresponds to one AMap page. The value of each byte indicates the longest number of free bits found in the corresponding AMap page. Generally, because each AMap covers about 250KB of data, each FMap page (496 bytes) covers around 125MB of data.

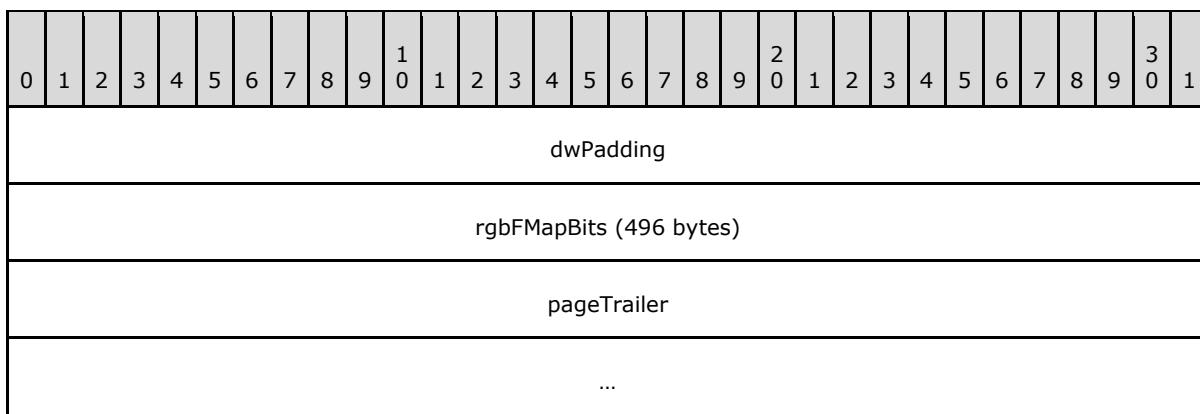

Implementations SHOULD NOT use FMaps. The Density List SHOULD be used for location free space. <[15](#)> However, the presence of FMap pages at the correct intervals MUST be preserved, and all corresponding checksums MUST be maintained for a PST file to remain valid.

### 2.2.2.7.5.1 FMAPPAGE

Unicode:

ANSI:

...
-----

**rgbFMapBits (496 bytes):** FMap data. Each byte represents the maximum number of contiguous "0" bits in the corresponding AMap (up to 16KB).

**dwPadding (ANSI only, 4 bytes):** Unused padding; MUST be set to Zero (0).

**pageTrailer (Unicode: 16 bytes; ANSI: 12 bytes):** A PAGETRAILER structure (section [2.2.2.7.1](#)). The **ptype** subfield of **pageTrailer** MUST be set to **ptypeFMap**. The other subfields of **pageTrailer** MUST be set as specified in section [2.2.2.7.1](#).

## 2.2.2.7.6 FPMAP (Free Page Map) Page

The general layout of an FPMAP is identical to that of an AMap, except that each bit in the FPMAP corresponds to a PMap page, and the value of the bit indicates whether there are any free pages within that PMap page. With each PMap covering about 2MB and an FPMAP page at 496 bytes, an FPMAP page covers about 8GB of space.

Implementations SHOULD NOT use FPMAPs. The Density List SHOULD be used for location free space. <[16](#)> However, the presence of FPMAP pages at the correct intervals MUST be preserved, and all corresponding checksums MUST be maintained for a PST file to remain valid.

### 2.2.2.7.6.1 FPMAPPAGE

Unicode only:

0	1	2	3	4	5	6	7	8	9	1	0	1	2	3	4	5	6	7	8	9	2	0	1	2	3	4	5	6	7	8	9	3	0	1
rgbFPMAPBits (496 bytes)																																		
pageTrailer (16 bytes)																																		

**rgbFPMAPBits (496 bytes):** FPMAP data. Each bit corresponds to a PMap page. If the  $n^{\text{th}}$  bit is set to "0", then the  $n^{\text{th}}$  PMap page from the beginning of the PST File has free pages. If the  $n^{\text{th}}$  bit is set to "1", then the  $n^{\text{th}}$  PMap page has no free pages.

**pageTrailer (Unicode: 16 bytes; ANSI: 12 bytes):** A PAGETRAILER structure (section [2.2.2.7.1](#)). The **ptype** subfield of **pageTrailer** MUST be set to **ptypeFPMAP**. The other subfields of **pageTrailer** MUST be set as specified in section [2.2.2.7.1](#).

## 2.2.2.7 BTrees

BTrees are widely used throughout the PST file format. In the NDB Layer, BTrees are the building blocks for the NBT and BBT, which are used to quickly navigate and search nodes and blocks. The PST file format uses a general BTTree implementation that supports up to 8 intermediate levels.

### 2.2.2.7.7.1 BTPAGE

A BTPAGE structure implements a generic BTTree using 512-byte pages.

Unicode:

0	1	2	3	4	5	6	7	8	9	1	0	1	2	3	4	5	6	7	8	9	2	0	1	2	3	4	5	6	7	8	9	3	0	1																					
rgentries (488 bytes)																																																							
cEnt								cEntMax								cbEnt								cLevel																															
dwPadding																																																							
pageTrailer (16 bytes)																																																							

ANSI:

0	1	2	3	4	5	6	7	8	9	1	0	1	2	3	4	5	6	7	8	9	2	0	1	2	3	4	5	6	7	8	9	3	0	1																					
rgentries (492 bytes)																																																							
cEnt								cEntMax								cbEnt								cLevel																															
dwPadding																																																							
pageTrailer																																																							
...																																																							
...																																																							

**rgentries (Unicode: 488 bytes; ANSI: 492 bytes):** Entries of the BTTree array. The entries in the array depend on the value of the **cLevel** field. If **cLevel** is greater than 0, then each entry in the array is of type BTENTRY. If **cLevel** is 0, then each entry is either of type BBTENTRY or NBTENTRY, depending on the **ptype** of the page.

**cEnt (1 byte):** The number of BTTree entries stored in the page data.

**cEntMax (1 byte):** The maximum number of entries that can fit inside the page data.

**cbEnt (1 byte):** The size of each BTTree entry, in bytes. Note that in some cases, **cbEnt** can be greater than the corresponding size of the corresponding **rgentries** structure because of alignment or other considerations. Implementations MUST use the size specified in **cbEnt** to advance to the next entry.

BTree Type	cLevel	rgentries structure	cbEnt (bytes)
NBT	0	NBTENTRY	ANSI: 16, Unicode: 32
	> 0	BTENTRY	ANSI: 12, Unicode: 24
BBT	0	BBTENTRY	ANSI: 12, Unicode: 24
	> 0	BTENTRY	ANSI: 12, Unicode: 24

**cLevel (1 byte):** The depth level of this page. Leaf pages have a level of 0, whereas intermediate pages have a level greater than 0. This value determines the type of the entries in **rgentries**, and is interpreted as unsigned.

**dwPadding (4 bytes):** Padding; MUST be set to zero (0).

**pageTrailer (Unicode: 16 bytes; ANSI: 12 bytes):** A PAGETRAILER structure (section [2.2.2.7.1](#)). The **ptype** subfield of **pageTrailer** MUST be set to **ptypeBBT** for a Block BTree page, or **ptypeNBT** for a Node BTree page. The other subfields of **pageTrailer** MUST be set as specified in section [2.2.2.7.1](#).

#### 2.2.2.7.7.2 BTENTRY (Intermediate Entries)

BTENTRY records contain a key value (NID or BID) and a reference to a child BTPAGE page in the BTree.

Unicode:

0	1	2	3	4	5	6	7	8	9	1	0	1	2	3	4	5	6	7	8	9	2	0	1	2	3	4	5	6	7	8	9	3	0	1
btkey																																		
...																																		
<b>BREF (16 bytes)</b>																																		

ANSI:

0	1	2	3	4	5	6	7	8	9	1	0	1	2	3	4	5	6	7	8	9	2	0	1	2	3	4	5	6	7	8	9	3	0	1
btkey																																		
<b>BREF</b>																																		
...																																		

**btkey (Unicode: 8 bytes; ANSI: 4 bytes):** The key value associated with this BTENTRY. All the entries in the child BTPAGE referenced by **BREF** have key values greater than or equal to this key

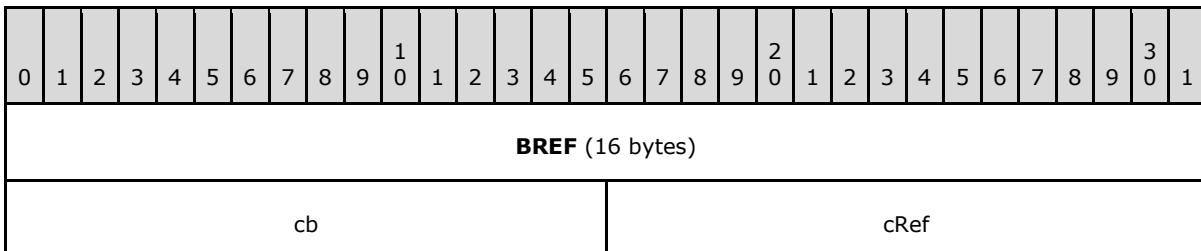

value. The **btkey** is either a NID (zero extended to 8 bytes for Unicode PSTs) or a BID, depending on the **ptype** of the page.

**BREF (Unicode: 16 bytes; ANSI: 8 bytes):** BREF structure (section [2.2.2.4](#)) that points to the child BTPAGE.

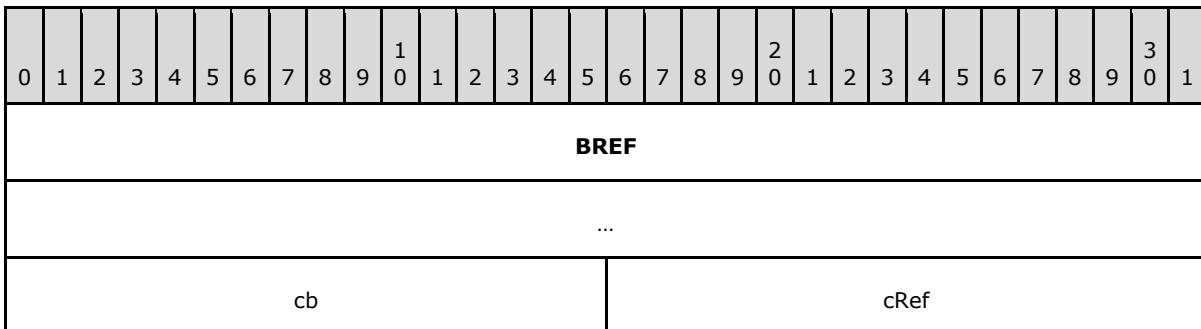

### 2.2.2.7.7.3 BBTENTRY (Leaf BBT Entry)

BBTENTRY records contain information about blocks and are found in BTPAGES with **cLevel** equal to 0, with the **ptype** of **ptypeBBT**. These are the leaf entries of the BBT.

Unicode:

ANSI:

**BREF (Unicode: 16 bytes; ANSI: 8 bytes):** BREF structure (section [2.2.2.4](#)) that contains the BID and IB of the block that the BBTENTRY references.

**cb (2 bytes):** The count of bytes of the raw data contained in the block referenced by **BREF** excluding the block trailer and alignment padding, if any.

**cRef (2 bytes):** Reference count indicating the count of references to this block. See section [2.2.2.7.7.3.1](#) regarding how reference counts work.

#### 2.2.2.7.7.3.1 Reference Counts

To improve storage efficiency, the NDB supports single-instancing by allowing multiple entities to reference the same data block. This is supported at the BBT level by having reference counts for blocks.

For example, when a node is copied, a new node is created with a new NID, but instead of making a separate copy of the entire contents of the node, the new node simply references the existing immediate data and subnode blocks by incrementing the reference count of each block.

The single-instance is only broken when the data referenced needs to be changed by a referencing node. This requires creation of a new block into which the new data is written and the reference count to the original block is decremented. When the reference count of a block reaches one, then the block is no longer in use and is marked as "Free" in the corresponding AMap. Finally, the corresponding leaf BBT entry is removed from the BBT.

In addition to the BBTENTRY, other types of structures can also hold references to a block. The following is a list of structures that can hold reference counts to a block:

- Leaf BBTENTRY – any leaf BBT entry that points to a BID holds a reference count to it.
- NBTENTRY – a reference count is held if a block is referenced in the **bidData** or **bidSub** fields of a NBTENTRY.
- SLBLOCK – a reference count is held if a block is referenced in the **bidData** or **bidSub** fields of an SLENTRY.
- Data tree – a reference count is held if a block is referenced in an **rgbid** slot of an XBLOCK.

For example, consider a node called Node1. The data block of Node1 has a reference count of 2 (BBTENTRY and Node1's NBTENTRY.**bidData**). If a copy of Node1 is made (Node2), then the block's reference count becomes 3 (Node2's NBTENTRY.**bidData**). If a change is made to Node2's data, then a new data block is created for the modified copy with a reference count of 2 (BBTENTRY, Node2's NBTENTRY.**bidData**), and the reference count of Node1's data block returns to 2 (BBTENTRY, Node1's NBTENTRY.**bidData**).

#### 2.2.2.7.7.4 NBTENTRY (Leaf NBT Entry)

NBTENTRY records contain information about nodes and are found in BTPAGES with **cLevel** equal to 0, with the **ptype** of **ptypeNBT**. These are the leaf entries of the NBT.

Unicode:

0	1	2	3	4	5	6	7	8	9	1	0	1	2	3	4	5	6	7	8	9	2	0	1	2	3	4	5	6	7	8	9	3	0	1
nid																																		
...																																		
bidData																																		
...																																		
bidSub																																		
...																																		
nidParent																																		

ANSI:

0	1	2	3	4	5	6	7	8	9	1	0	1	2	3	4	5	6	7	8	9	2	0	1	2	3	4	5	6	7	8	9	3	0	1
nid																																		
bidData																																		
bidSub																																		
nidParent																																		

**nid (Unicode: 8 bytes; ANSI: 4 bytes):** The NID (section [2.2.2.1](#)) of the entry. Note that the NID is a 4-byte value for both Unicode and ANSI formats. However, to stay consistent with the size of the **btkey** member in BTENTRY, the 4-byte NID is extended to its 8-byte equivalent for Unicode PST files.

**bidData (Unicode: 8 bytes; ANSI: 4 bytes):** The BID of the data block for this node.

**bidSub (Unicode: 8 bytes; ANSI: 4 bytes):** The BID of the subnode block for this node. If this value is zero (0), then a subnode block does not exist for this node.

**nidParent (4 bytes):** If this node represents a child of a Folder object defined in the Messaging Layer, then this value is nonzero and contains the NID of the parent Folder object's node. Otherwise, this value is zero (0). See section [2.2.2.7.7.4.1](#) for more information. This field is not interpreted by any structure defined at the NDB Layer.

#### 2.2.2.7.7.4.1 Parent NID

A specific challenge exists when a simple node database is used to represent hierarchical concepts such as a tree of Folder objects where top-level nodes are disjoint items that do not contain hierarchical semantics. While subnodes have a hierarchical structure, the fact that internal subnodes are not addressable outside of the NDB Layer makes them unsuitable for this purpose.

The concept of a parent NID (**nidParent**) is introduced to address this challenge, providing a simple and efficient way for each Folder object node to point back to its parent Folder object node in the hierarchy. This link enables traversing up the Folder object tree to find its parent Folder objects, which is necessary and common for many Folder object-related operations, without having to read the raw data associated with each node.

The parent NID concept described here is separate from the node/subnode relationship. The parent NID, as described here has no meaning to the NDB Layer and is merely maintained as an optimization for the Messaging Layer.

#### 2.2.2.8 Blocks

Blocks are the fundamental units of data storage at the NDB Layer. Blocks are always assigned in sizes that are multiples of 64 bytes and are always aligned on 64-byte boundaries. The maximum size of any block is 8KB (8192 bytes).

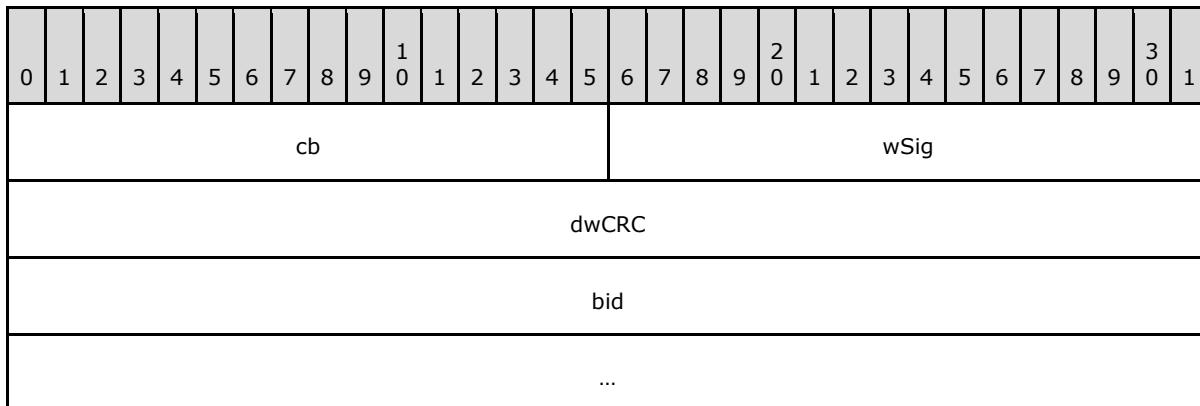

Similar to pages, each block stores its metadata in a block trailer placed at the very end of the block so that the end of the trailer is aligned with the end of the block.

Blocks generally fall into one of two categories: data blocks and subnode blocks. Data blocks are used to store raw data, where subnode blocks are used to represent nodes contained within a node.

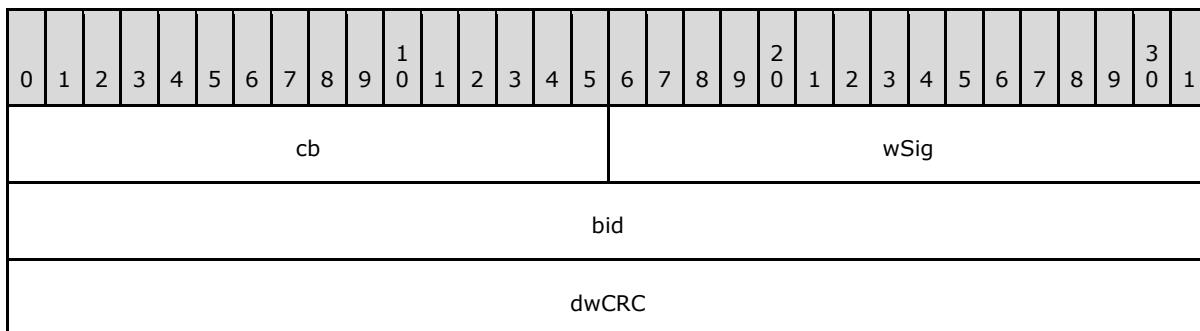

The storage capacity of each data block is the size of the data block (from 64 to 8192 bytes) minus the size of the trailer block.

#### 2.2.2.8.1 BLOCKTRAILER

Unicode:

ANSI:

**cb (2 bytes):** The amount of data, in bytes, contained within the data section of the block. This value does not include the block trailer or any unused bytes that can exist after the end of the data and before the start of the block trailer.

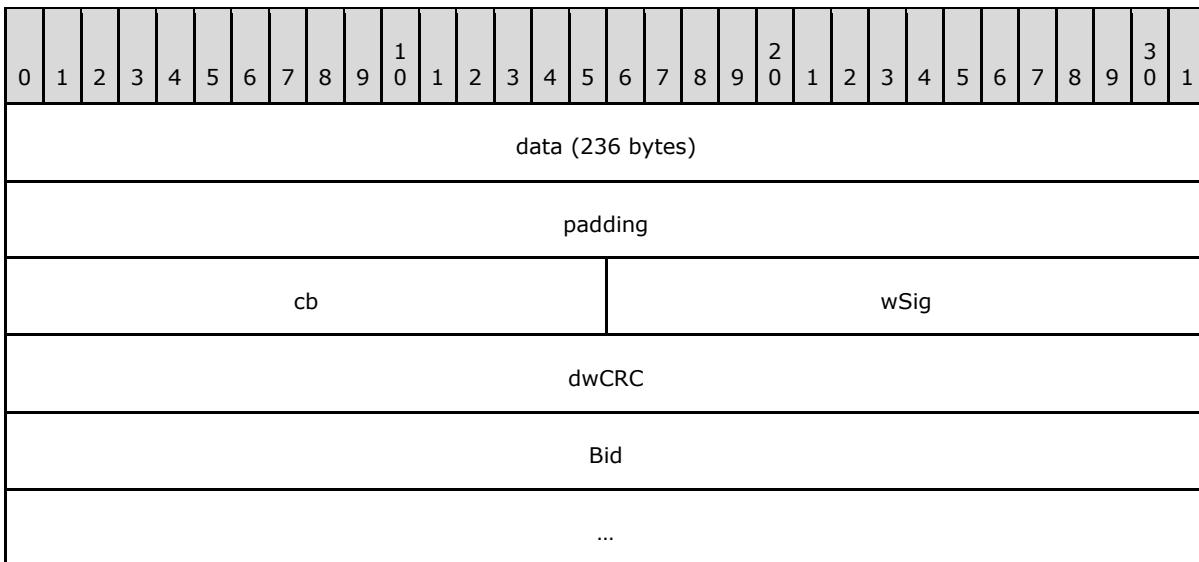

**wSig (2 bytes):** Block signature. See section [5.5](#) for the algorithm to calculate the block signature.

**dwCRC (4 bytes):** 32-bit CRC of the **cb** bytes of raw data, see section [5.3](#) for the algorithm to calculate the CRC.

**bid (Unicode: 8 bytes; ANSI 4 bytes):** The BID (section [2.2.2.2](#)) of the data block.

### 2.2.2.8.2 Anatomy of a Block

The following example attempts to illustrate the anatomy of a block allocated at absolute file offset 0x5000 to store 236 (0xEC) bytes of raw data in a Unicode PST file.

Given the raw data size of 236 bytes and a block trailer size of 16 bytes, the smallest multiple of 64 that can hold both items is 256 (0x100). Thus, the size of the data block required is 256 bytes. However, the raw data and the trailer only add up to 252 bytes, which results in a 4-byte gap between the end of the raw data and the beginning of the trailer. This gap of "wasted space" is necessitated by the alignment of the trailer block with respect to the end of the block and can be as large as 63 bytes.

Because the data in the **padding** field is undetermined (that is, not guaranteed to be zero-filled), implementers MUST NOT include unused data in CRC calculations. In this particular case, the value of **cb** is 236 (not 240) and the calculation for the value in **dwCRC** MUST NOT include the 4 bytes of "unused" data in the **padding** field.

The data contained in the data section of most blocks within a PST file have no meaning to the structures defined at the NDB Layer. However, some blocks contain metadata that is interpreted by the NDB Layer.

### 2.2.2.8.3 Block Types

Several types of blocks are defined at the NDB Layer. The following table defines the block type mapping.

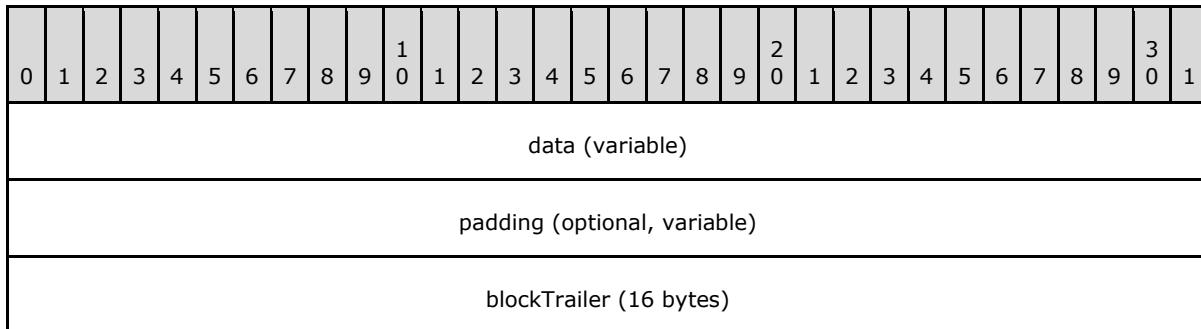

Block Type	Data Structure	Internal BID?	Header Level	Array Content
Data Tree	Data block	No	N/A	Bytes
	XBLOCK	Yes	1	XBLOCK reference
	XXBLOCK		2	Data block reference
Subnode BTree data	SLBLOCK		0	SLENTRY

Block Type	Data Structure	Internal BID?	Header Level	Array Content
	SIBLOCK		1	SIENTRY

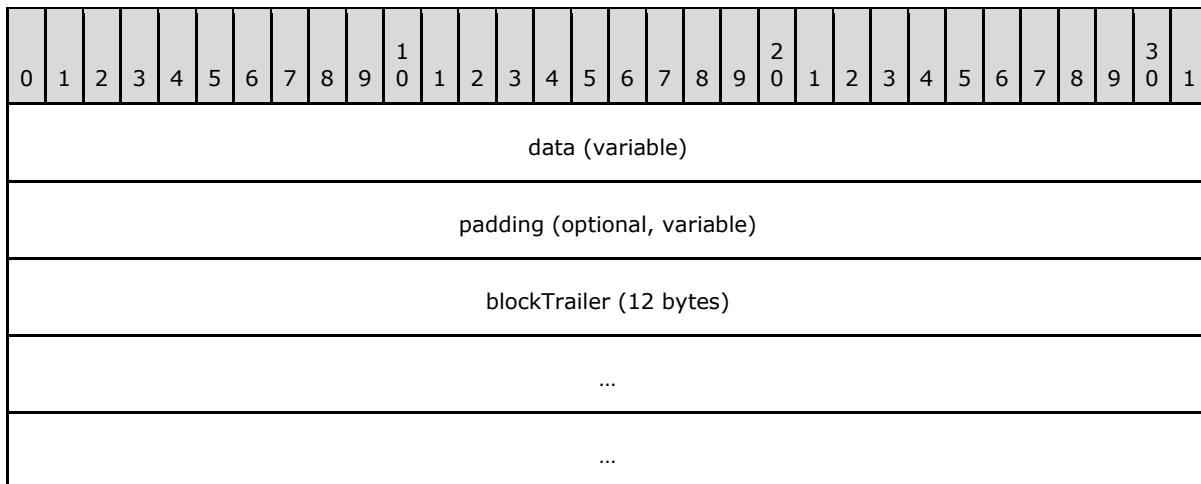

### 2.2.2.8.3.1 Data Blocks

A data block is a block that is "External" (that is, not marked "Internal") and contains data streamed from higher layer structures. The data contained in data blocks have no meaning to the structures defined at the NDB Layer.

Unicode:

ANSI:

**data (variable):** The value of this field SHOULD be treated as an opaque binary large object (BLOB) by the NDB Layer. The size of this field is indicated by the **cb** subfield of the **blockTrailer** field.

**padding (optional, variable):** This field is present if the size of the **data** field plus the size of the **blockTrailer** field is not a multiple of 64. The size of this field is the smallest number of bytes required to make the size of the data block a multiple of 64. Implementations MUST ignore this field.

**blockTrailer (Unicode: 16 bytes; ANSI: 12 bytes):** A BLOCKTRAILER structure (section [2.2.2.8.1](#)).

### 2.2.2.8.3.1.1 Data Block Encoding/Obfuscation

A special case exists when a PST file is configured to encode its contents. In that case, the NDB Layer encodes the **data** field of data blocks to obfuscate the data using one of two keyless ciphers. Section 5.1 and section 5.2 contain further information about the two cipher algorithms used to encode the data. Only the **data** field is encoded. The **padding** and **blockTrailer** are not encoded.

### 2.2.2.8.3.2 Data Tree

A data tree collectively refers to all the elements that are used to store data. In the simplest case, a data tree consists of a single data block, which can hold up to 8,176 bytes. If the data is more than 8,176 bytes, a construct using XBLOCKS and XXBLOCKS is used to store the data in a series of data blocks arranged in a tree format. The layout of the XBLOCK and XXBLOCK structures are defined in the following sections.

#### 2.2.2.8.3.2.1 XBLOCK

XBLOCKs are used when the data associated with a node data that exceeds 8,176 bytes in size. The XBLOCK expands the data that is associated with a node by using an array of BIDs that reference data blocks that contain the data stream associated with the node. A BLOCKTRAILER is present at the end of an XBLOCK, and the end of the BLOCKTRAILER MUST be aligned on a 64-byte boundary.

Unicode:

0	1	2	3	4	5	6	7	8	9	1	0	1	2	3	4	5	6	7	8	9	2	0	1	2	3	4	5	6	7	8	9	3	0	1					
btype								cLevel								cEnt																							
lcbTotal																																							
rgbid (variable)																																							
...																																							
...																																							
rgbPadding (optional, variable)																																							
blockTrailer (16 bytes)																																							

ANSI:

0	1	2	3	4	5	6	7	8	9	1	0	1	2	3	4	5	6	7	8	9	2	0	1	2	3	4	5	6	7	8	9	3	0	1
btype								cLevel								cEnt																		
...																																		

lcbTotal
rgbid (variable)
...
...
rgbPadding (optional, variable)
blockTrailer
...
...

**btype (1 byte):** Block type; MUST be set to 0x01 to indicate an XBLOCK or XXBLOCK.

**cLevel (1 byte):** MUST be set to 0x01 to indicate an XBLOCK.

**cEnt (2 bytes):** The count of BID entries in the XBLOCK.

**lcbTotal (4 bytes):** Total count of bytes of all the external data stored in the data blocks referenced by XBLOCK.

**rgbid (variable):** Array of BIDs that reference data blocks. The size is equal to the number of entries indicated by **cEnt** multiplied by the size of a BID (8 bytes for Unicode PST files, 4 bytes for ANSI PST Files).

**rgbPadding (optional, variable):** This field is present if the total size of all of the other fields is not a multiple of 64. The size of this field is the smallest number of bytes required to make the size of the XBLOCK a multiple of 64. Implementations MUST ignore this field.

**blockTrailer (ANSI: 12 bytes; Unicode: 16 bytes):** A BLOCKTRAILER structure (section [2.2.2.8.1](#)).

### 2.2.2.8.3.2.2 XXBLOCK

The XXBLOCK further expands the data that is associated with a node by using an array of BIDs that reference XBLOCKS. A BLOCKTRAILER is present at the end of an XXBLOCK, and the end of the BLOCKTRAILER MUST be aligned on a 64-byte boundary.

Unicode:

0	1	2	3	4	5	6	7	8	9	1	0	1	2	3	4	5	6	7	8	9	2	0	1	2	3	4	5	6	7	8	9	3	0	1
btype										cLevel										cEnt														

lcbTotal
rgbid (variable)
...
...
rgbPadding (optional, variable)
blockTrailer (16 bytes)

ANSI:

0	1	2	3	4	5	6	7	8	9	1	0	1	2	3	4	5	6	7	8	9	2	0	1	2	3	4	5	6	7	8	9	3	0	1				
btype										cLevel										cEnt																		
lcbTotal																																						
rgbid (variable)																																						
...																																						
...																																						
rgbPadding (optional, variable)																																						
blockTrailer																																						
...																																						
...																																						

**btype (1 byte):** Block type; MUST be set to 0x01 to indicate an XBLOCK or XXBLOCK.

**cLevel (1 byte):** MUST be set to 0x02 to indicate and XXBLOCK.

**cEnt (2 bytes):** The count of BID entries in the XXBLOCK.

**lcbTotal (4 bytes):** Total count of bytes of all the external data stored in XBLOCKS under this XXBLOCK.

**rgbid (variable):** Array of BIDs that reference XBLOCKS. The size is equal to the number of entries indicated by **cEnt** multiplied by the size of a BID (8 bytes for Unicode PST files, 4 bytes for ANSI PST Files).

**rgbPadding (optional, variable):** This field is present if the total size of all of the other fields is not a multiple of 64. The size of this field is the smallest number of bytes required to make the size of the XBLOCK a multiple of 64. Implementations MUST ignore this field.

**blockTrailer (ANSI: 12 bytes; Unicode: 16 bytes):** A BLOCKTRAILER structure (section [2.2.2.8.1](#)).

### 2.2.2.8.3.3 Subnode BTREE

The subnode BTREE collectively refers to all the elements that make up a subnode. The subnode BTREE is a BTREE that is made up of SIBLOCK and SLBLOCK structures, which contain SIENTRY and SLENTRY structures, respectively. These structures are defined in the following sections.

#### 2.2.2.8.3.3.1 SLBLOCKS

An SLBLOCK is a block that contains an array of SLENTRYs. It is used to reference the subnodes of a node.

##### 2.2.2.8.3.3.1.1 SLENTRY (Leaf Block Entry)

SLENTRY are records that refer to internal subnodes of a node.

Unicode:

0	1	2	3	4	5	6	7	8	9	1	0	1	2	3	4	5	6	7	8	9	2	0	1	2	3	4	5	6	7	8	9	3	0	1
nid																																		
...																																		
bidData																																		
...																																		
bidSub																																		
...																																		

ANSI:

0	1	2	3	4	5	6	7	8	9	1	0	1	2	3	4	5	6	7	8	9	2	0	1	2	3	4	5	6	7	8	9	3	0	1
nid																																		
bidData																																		
bidSub																																		

**nid (Unicode: 8 bytes; ANSI: 4 bytes):** Local NID of the child subnode. This NID is guaranteed to be unique only within the parent node.

**bidData (Unicode: 8 bytes; ANSI: 4 bytes):** The BID of the data block associated with the child subnode.

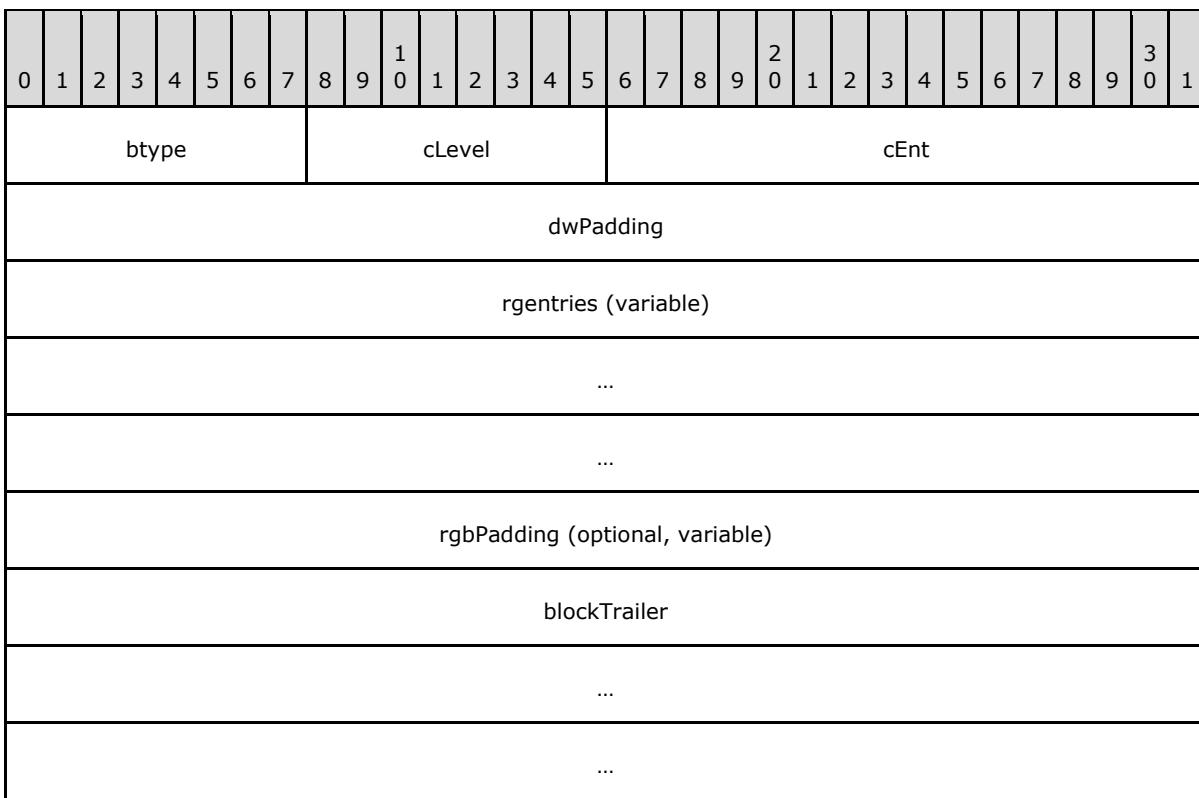

**bidSub (Unicode: 8 bytes; ANSI: 4 bytes):** If nonzero, the BID of the child subnode of this child subnode.

### 2.2.2.8.3.3.1.2 SLBLOCK

Unicode:

0	1	2	3	4	5	6	7	8	9	1	0	1	2	3	4	5	6	7	8	9	2	0	1	2	3	4	5	6	7	8	9	3	0	1					
btype								cLevel								cEnt																							
dwPadding																																							
rgentries (variable)																																							
...																																							
rgbPadding (optional, variable)																																							
blockTrailer (16 bytes)																																							

ANSI:

**btype (1 byte):** Block type; MUST be set to 0x02.

**cLevel (1 byte):** MUST be set to 0x00.

**cEnt (2 bytes):** The number of SLENTRYs in the SLBLOCK.

**dwPadding (4 bytes):** Padding; MUST be set to zero (0).

**rgentries (variable size):** Array of SLENTRY structures. The size is equal to the number of entries indicated by **cEnt** multiplied by the size of an SLENTRY (24 bytes for Unicode PST files, 12 bytes for ANSI PST Files).

**rgbPadding (optional, variable):** This field is present if the total size of all of the other fields is not a multiple of 64. The size of this field is the smallest number of bytes required to make the size of the SLBLOCK a multiple of 64. Implementations MUST ignore this field.

**blockTrailer (ANSI: 12 bytes; Unicode: 16 bytes):** A BLOCKTRAILER structure (section [2.2.2.8.1](#)).

### 2.2.2.8.3.3.2 SIBLOCKs

An SIBLOCK is a block that contains an array of SIENTRYs. It is used to extend the number of subnodes that a node can reference by chaining SLBLOCKs.

#### 2.2.2.8.3.3.2.1 SIENTRY (Intermediate Block Entry)

SIENTRY are intermediate records that point to SLBLOCKs.

Unicode:

0	1	2	3	4	5	6	7	8	9	1	0	1	2	3	4	5	6	7	8	9	2	0	1	2	3	4	5	6	7	8	9	3	0	1
nid																																		
...																																		
bid																																		
...																																		

ANSI:

0	1	2	3	4	5	6	7	8	9	1	0	1	2	3	4	5	6	7	8	9	2	0	1	2	3	4	5	6	7	8	9	3	0	1
nid																																		
bid																																		

**nid (Unicode: 8 bytes; ANSI: 4 bytes):** The key NID value to the next-level child block. This NID is only unique within the parent node. The NID is extended to 8 bytes in order for Unicode PST files to follow the general convention of 8-byte indices (see section [2.2.2.7.7.4](#) for details).

**bid (Unicode: 8 bytes; ANSI: 4 bytes):** The BID of the SLBLOCK.

### 2.2.2.8.3.3.2.2 SIBLOCK

Unicode:

0	1	2	3	4	5	6	7	8	9	1	0	1	2	3	4	5	6	7	8	9	2	0	1	2	3	4	5	6	7	8	9	3	0	1								
btype											cLevel											cEnt																				
dwPadding																																										
rgentries (variable)																																										
...																																										
...																																										

rgbPadding (optional, variable)		
blockTrailer (16 bytes)		
ANSI:		
btype		
cLevel		
cEnt		
dwPadding		
rgentries (variable)		
...		
...		
rgPadding (optional, variable)		
blockTrailer		
...		
...		

**btype (1 byte):** Block type; MUST be set to 0x02.

**cLevel (1 byte):** MUST be set to 0x01.

**cEnt (2 bytes):** The number of SIENTRYs in the SIBLOCK.

**dwPadding (4 bytes):** Padding; MUST be set to zero (0).

**rgentries (variable size):** Array of SIENTRY structures. The size is equal to the number of entries indicated by **cEnt** multiplied by the size of an SIENTRY (16 bytes for Unicode PST files, 8 bytes for ANSI PST Files).

**rgbPadding (optional, variable):** This field is present if the total size of all of the other fields is not a multiple of 64. The size of this field is the smallest number of bytes required to make the size of the SIBLOCK a multiple of 64. Implementations MUST ignore this field.

**blockTrailer (ANSI: 12 bytes; Unicode: 16 bytes):** A BLOCKTRAILER structure (section [2.2.2.8.1](#)).

## 2.3 LTP Layer

The LTP Layer builds on top of the NDB infrastructure to provide the structured storage elements that are required to represent complex Messaging-related objects such as Folder objects, Message objects and Attachment objects.

The LTP defines a heap on an NDB node as well as a BTree that is defined within the heap structure.

The LTP uses these abstractions to further define Property Contexts and Table Contexts which represent collections of property-value pairs and tables consisting of rows of columns, respectively.

### 2.3.1 HN (Heap-on-Node)

The Heap-on-Node defines a standard heap over a node's data stream. Taking advantage of the flexible structure of the node, the organization of the heap data can take on several forms, depending on how much data is stored in the heap.

For heaps whose size exceed the amount of data that can fit in one data block, the first data block in the HN contains a full header record and a trailer record. With the exception of blocks that require an HNBIMAPHDR structure, subsequent data blocks only have an abridged header and a trailer. This is explained in more detail in the following sections. Because the heap is a structure that is defined at a higher layer than the NDB, the heap structures are written to the external data sections of data blocks and do not use any information from the data block's NDB structure.

#### 2.3.1.1 HID

A HID is a 4-byte value that identifies an item allocated from the heap. The value is unique only within the heap itself. The following is the structure of a HID.

Unicode / ANSI:

0	1	2	3	4	5	6	7	8	9	1	0	1	2	3	4	5	6	7	8	9	2	0	1	2	3	4	5	6	7	8	9	3	0	1
hidType					hidIndex											hidBlockIndex																		

**hidType (5 bits):** HID Type; MUST be set to 0 (NID\_TYPE\_HID) to indicate a valid HID.

**hidIndex (11 bits):** HID index. This is the 1-based index value that identifies an item allocated from the heap node. This value MUST NOT be zero (0).

**hidBlockIndex (16 bits):** This is the 0-based data block index. This number indicates the 0-based index of the data block in which this heap item resides.

#### 2.3.1.2 HNHDR

The HNHDR record resides at the beginning of the first data block in the HN (a HN can span several blocks), which contains root information about the HN.

Unicode / ANSI:

0	1	2	3	4	5	6	7	8	9	1	0	1	2	3	4	5	6	7	8	9	2	0	1	2	3	4	5	6	7	8	9	3	0	1																
ibHnpm										bSig										bClientSig																														
hidUserRoot																																																		
rgbFillLevel																																																		

**ibHnpm (2 bytes):** The byte offset to the HN page Map record (section [2.3.1.5](#)), with respect to the beginning of the HNHDR structure.

**bSig (1 byte):** Block signature; MUST be set to 0xEC to indicate a HN.

**bClientSig (1 byte):** Client signature. This value describes the higher-level structure that is implemented on top of the HN. This value is intended as a hint for a higher-level structure and has no meaning for structures defined at the HN level. The following values are pre-defined for **bClientSig**. All other values not described in the following table are reserved and MUST NOT be assigned or used.

Value	Friendly Name	Meaning
0x6C	bTypeReserved1	Reserved
0x7C	bTypeTC	Table Context (TC/HN)
0x8C	bTypeReserved2	Reserved
0x9C	bTypeReserved3	Reserved
0xA5	bTypeReserved4	Reserved
0xAC	bTypeReserved5	Reserved
0xB5	bTypeBTH	BTree-on-Heap (BTH)
0xBC	bTypePC	Property Context (PC/BTH)
0xCC	bTypeReserved6	Reserved

**hidUserRoot (4 bytes):** HID that points to the User Root record. The User Root record contains data that is specific to the higher level.

**rgbFillLevel (4 bytes):** Per-block Fill Level Map. This array consists of eight 4-bit values that indicate the fill level for each of the first 8 data blocks (including this header block). If the HN has fewer than 8 data blocks, then the values corresponding to the non-existent data blocks MUST be set to zero (0). The following table explains the values indicated by each 4-bit value.

Value	Friendly Name	Meaning
0x0	FILL_LEVEL_EMPTY	At least 3584 bytes free / data block does not exist
0x1	FILL_LEVEL_1	2560-3584 bytes free

<b>Value</b>	<b>Friendly Name</b>	<b>Meaning</b>
0x2	FILL_LEVEL_2	2048-2560 bytes free
0x3	FILL_LEVEL_3	1792-2048 bytes free
0x4	FILL_LEVEL_4	1536-1792 bytes free
0x5	FILL_LEVEL_5	1280-1536 bytes free
0x6	FILL_LEVEL_6	1024-1280 bytes free
0x7	FILL_LEVEL_7	768-1024 bytes free
0x8	FILL_LEVEL_8	512-768 bytes free
0x9	FILL_LEVEL_9	256-512 bytes free
0xA	FILL_LEVEL_10	128-256 bytes free
0xB	FILL_LEVEL_11	64-128 bytes free
0xC	FILL_LEVEL_12	32-64 bytes free
0xD	FILL_LEVEL_13	16-32 bytes free
0xE	FILL_LEVEL_14	8-16 bytes free
0xF	FILL_LEVEL_FULL	Data block has less than 8 bytes free

### 2.3.1.3 HNPAGEHDR

This is the header record used in subsequent data blocks of the HN that do not require a new Fill Level Map (see next section). This is only used when multiple data blocks are present.

Unicode / ANSI:

<b>0</b>	<b>1</b>	<b>2</b>	<b>3</b>	<b>4</b>	<b>5</b>	<b>6</b>	<b>7</b>	<b>8</b>	<b>9</b>	<b>10</b>	<b>1</b>	<b>2</b>	<b>3</b>	<b>4</b>	<b>5</b>
ibHnpm															

**ibHnpm (2 bytes):** The bytes offset to the HNPAGEMAP record (section [2.3.1.5](#)), with respect to the beginning of the HNPAGEHDR structure.

### 2.3.1.4 HNBITMAPHDR

Beginning with the eighth data block, a new Fill Level Map is required. An HNBITMAPHDR fulfills this requirement. The Fill Level Map in the HNBITMAPHDR can map 128 blocks. This means that an HNBITMAPHDR appears at data block 8 (the first data block is data block 0) and thereafter every 128 blocks. (that is, data block 8, data block 136, data block 264, and so on).

Unicode / ANSI:

0	1	2	3	4	5	6	7	8	9	1	0	1	2	3	4	5	6	7	8	9	2	0	1	2	3	4	5	6	7	8	9	3	0	1
ibHnpm																rgbFillLevel (64 bytes)																		
...																...																		
...																																		
...																																		

**ibHnpm (2 bytes):** The byte offset to the HNPAGEMAP record (section [2.3.1.5](#)) relative to the beginning of the HNPAGEHDR structure.

**rgbFillLevel (64 bytes):** Per-block Fill Level Map. This array consists of one hundred and twenty-eight (128) 4-bit values that indicate the fill level for the next 128 data blocks (including this data block). If the HN has fewer than 128 data blocks after this data block, then the values corresponding to the non-existent data blocks MUST be set to zero (0). See **rgbFillLevel** in section [2.3.1.2](#) for possible values.

### 2.3.1.5 HNPAGEMAP

The HNPAGEMAP record is located at the end of each HN block immediately before the block trailer. It contains the information about the allocations in the page. The HNPAGEMAP is located using the **ibHnpm** field in the HNHDR, HNPAGEHDR and HNBITMAPHDR records.

Unicode / ANSI:

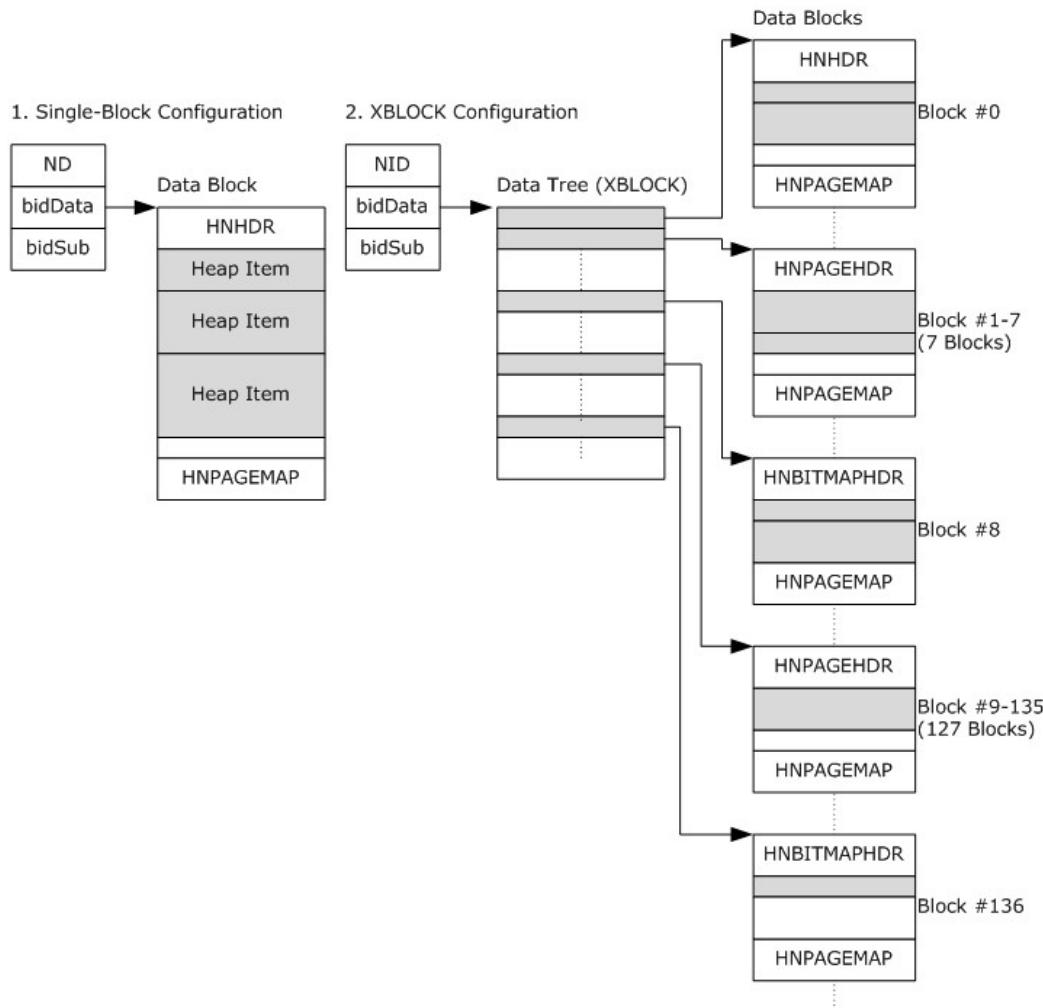

0	1	2	3	4	5	6	7	8	9	1	0	1	2	3	4	5	6	7	8	9	2	0	1	2	3	4	5	6	7	8	9	3	0	1
cAlloc																cFree																		
rgibAlloc (variable)																																		

**cAlloc (2 bytes):** Allocation count. This represents the number of items (allocations) in the HN.

**cFree (2 bytes):** Free count. This represents the number of freed items in the HN.

**rgibAlloc (variable):** Allocation table. This contains **cAlloc** + 1 entries. Each entry is a WORD value that is the byte offset to the beginning of the allocation. An extra entry exists at the **cAlloc** + 1<sup>st</sup> position to mark the offset of the next available slot. Therefore, the n<sup>th</sup> allocation starts at offset **rgibAlloc[n]** (from the beginning of the HN header), and its size is calculated as: **rgibAlloc[n + 1] - rgibAlloc[n]** bytes.

### 2.3.1.6 Anatomy of HN Data Blocks

**Figure 4: Data Organization of a Heap Node**

The preceding example illustrates the data organization for a HN that consists of a single data block, and a HN that consists of multiple data blocks through the use of a data tree construct. Note that an XXBLOCK can be used if the space required exceeds the capacity of an XBLOCK.

#### 2.3.1.6.1 Single-block Configuration

The single-block HN consists of a single data block with an HNHDR header structure and an HNPAGEMAP trailer structure at the end. The diagram in section 2.3.1.6 also shows how all the items allocated from the heap are located in the space between the HNHDR and HNPAGEMAP structures.

#### 2.3.1.6.2 Data Tree Configuration

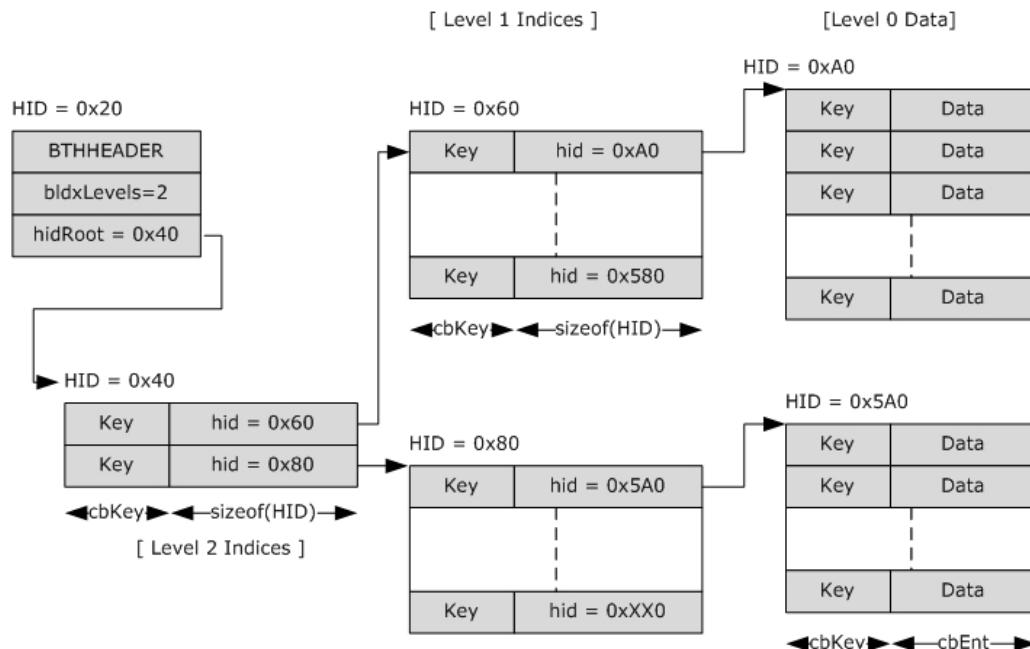

In the case of the multi-block HN, a data tree is used to fan out into multiple data blocks. An XXBLOCK is used if the HN exceeds the capacity of an XBLOCK, but the maximum number of blocks

is  $2^{16}$  because of the 16-bit capacity of **hidBlockIndex** (section 2.3.1.1). The first data block is identical to the single-block case. Because the HNHDR has eight Fill Level Map slots, the next seven blocks only have the abbreviated HNPAGEHDR header structure. The eighth block, however, only has an HNBITMAPHDR header structure because a new Fill Level Map is needed. Because HNBITMAPHDR has 128 slots, it is only required once every 128 blocks thereafter. All the blocks in-between have the HNPAGEHDR header instead.

In terms of data arrangement, the data tree case is an extension to the single-block case, where individual heap items are allocated from the leaf data blocks in a similar manner.

### 2.3.2 BTree-on-Heap (BTH)

A BTree-on-Heap implements a classic BTree on a heap node. A BTH consists of several parts: A header, the BTree records, and optional BTree data. The following diagram shows a high-level schematic of a BTH.

**Figure 5: Data Organization of a BTH**

The preceding diagram shows a BTH with two levels of indices. The top-level index (Key, HID) value pairs actually point to heap items that contain the Level 1 Indices, which, in turn, point to heap items that contain the leaf (Key, data) value pairs. Notice that each of the six boxes in the diagram actually represents six separate items allocated out of the same HN, as indicated by their associated HIDs.

#### 2.3.2.1 BTHHEADER

The BTHHEADER contains the BTH metadata, which instructs the reader how to access the other objects of the BTH structure.

Unicode / ANSI:

0	1	2	3	4	5	6	7	8	9	1	0	1	2	3	4	5	6	7	8	9	2	0	1	2	3	4	5	6	7	8	9	3	0	1
bType								cbKey								cbEnt								bIdxLevels										
hidRoot																																		

**bType (1 byte):** MUST be **bTypeBTH**.

**cbKey (1 byte):** Size of the BTree Key value, in bytes. This value MUST be set to 2, 4, 8, or 16.

**cbEnt (1 byte):** Size of the data value, in bytes. This MUST be greater than zero (0) and less than or equal to 32.

**bIdxLevels (1 byte):** Index depth. This number indicates how many levels of intermediate indices exist in the BTH. Note that this number is zero-based, meaning that a value of zero (0) actually means that the BTH has one level of indices. If this value is greater than zero (0), then its value indicates how many intermediate index levels are present.

**hidRoot (4 bytes):** This is the HID that points to the BTH entries for this BTHHEADER. The data consists of an array of BTH Records. This value is set to zero (0) if the BTH is empty.

### 2.3.2.2 Intermediate BTH (Index) Records

Index records do not contain actual data, but point to other index records or leaf records. The format of the intermediate index record is as follows. The number of index records can be determined based on the size of the heap allocation.

Unicode / ANSI:

0	1	2	3	4	5	6	7	8	9	1	0	1	2	3	4	5	6	7	8	9	2	0	1	2	3	4	5	6	7	8	9	3	0	1
key (variable)																hidNextLevel																		
...																																		

**key (variable):** This is the **key** of the first record in the next level index record array. The size of the **key** is specified in the **cbKey** field in the corresponding BTHHEADER structure (section [2.3.2.1](#)). The size and contents of the **key** are specific to the higher level structure that implements this BTH.

**hidNextLevel (4 bytes):** HID of the next level index record array. This contains the HID of the heap item that contains the next level index record array.

### 2.3.2.3 Leaf BTH (Data) Records

Leaf BTH records contain the actual data associated with each key entry. The BTH records are tightly packed (that is, byte-aligned), and each record is exactly **cbKey** + **cbEnt** bytes in size. The number of data records can be determined based on the size of the heap allocation.

Unicode / ANSI:

0	1	2	3	4	5	6	7	8	9	1	0	1	2	3	4	5	6	7	8	9	2	0	1	2	3	4	5	6	7	8	9	3	0	1
key (variable)																data (variable)																		
...																																		

**key (variable):** This is the key of the record. The size of the **key** is specified in the **cbKey** field in the corresponding BTHHEADER structure(section [2.3.2.1](#)). The size and contents of the **key** are specific to the higher level structure that implements this BTH.

**data (variable):** This contains the actual data associated with the **key**. The size of the data is specified in the **cbEnt** field in the corresponding BTHHEADER structure. The size and contents of the data are specific to the higher level structure that implements this BTH.

### 2.3.3 Property Context (PC)

The Property Context is built directly on top of a BTH. The existence of a PC is indicated at the HN level, where **bClientSig** is set to **bTypePC**. Implementation-wise, the PC is simply a BTH with **cbKey**=2 and **cbEnt**=6 (see section [2.3.3.3](#)). The following section explains the layout of a PC BTH record.

Each property is stored as an entry in the BTH. Accessing a specific property is just a matter of searching the BTH for a key that matches the **property identifier** of the desired property, as the following data structure illustrates.

#### 2.3.3.1 Accessing the PC BTHHEADER

The BTHHEADER structure of a PC is accessed through the **hidUserRoot** of the HNHDR structure of the containing HN.

#### 2.3.3.2 HNID

An HNID is a 32-bit hybrid value that represents either a HID or a NID. The determination is made by examining the **hidType** (or equivalently, **nidType**) value. The HNID refers to a HID if the **hidType** is NID\_TYPE\_HID. Otherwise, the HNID refers to a NID.

A HNID that refers to a HID indicates that the item is stored in the data block. An HNID that refers to a NID indicates that the item is stored in the subnode block, and the NID is the local NID under the subnode where the raw data is located.

#### 2.3.3.3 PC BTH Record

Unicode / ANSI:

0	1	2	3	4	5	6	7	8	9	1	0	1	2	3	4	5	6	7	8	9	2	0	1	2	3	4	5	6	7	8	9	3	0	1
wPropId																wPropType																		
...																																		

## dwValueHnid

**wPropId (2 bytes):** Property ID, as specified in [\[MS-OXCDATA\]](#) section 2.10. This is the upper 16 bits of the property tag value. This is a manifestation of the BTH record (section [2.3.2.3](#)) and constitutes the key of this record.

**wPropType (2 bytes):** **Property type.** This is the lower 16 bits of the property tag value, which identifies the type of data that is associated with the property. The complete list of property type values and their data sizes are specified in [\[MS-OXCDATA\]](#) section 2.12.1.

**dwValueHnid (4 bytes):** Depending on the data size of the property type indicated by **wPropType** and a few other factors, this field represents different values. The following table explains the value contained in **dwValueHnid** based on the different scenarios. In the event where the **dwValueHnid** value contains a HID or NID (section [2.3.3.2](#)), the actual data is stored in the corresponding heap or subnode entry, respectively.

Variable Size?	Fixed Data Size	NID_TYPE(dwValueHnid) == NID_TYPE_HID?	dwValueHnid
N	<= 4 bytes	-	Data Value
	> 4 bytes	Y	HID
Y	-	Y	HID (<= 3580 bytes)
		N	NID (subnode, > 3580 bytes)

### 2.3.3.4 Multi-Valued Properties

Multi-valued (MV) properties are properties that contain an array of values. A Multi-Valued property can be derived from any basic property type, for example: **PtypInteger32**, **PtypGuid**, **PtypString**, **PtypBinary** ([\[MS-OXCDATA\]](#) section 2.12.1). The value of an MV property is always stored using an HNID, and is encoded in a packed binary format. The following explains the data format for Multi-valued properties:

#### 2.3.3.4.1 MV Properties with Fixed-size Base Type

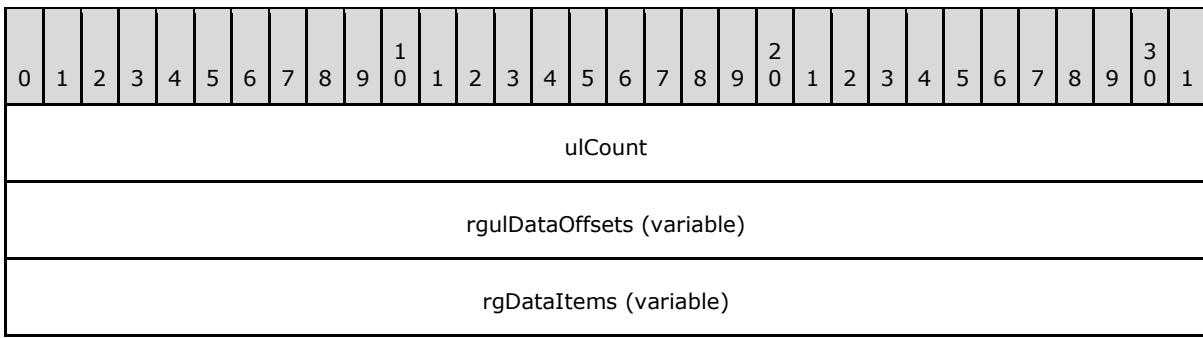

When an MV property contains elements of fixed size, such as **PtypInteger32** or **PtypGuid**, the data layout is very straightforward. The number of elements present is determined by dividing the size of the heap or node data size by the size of the data type. Each data element is aligned with respect to its own data type, which results in a tightly-packed array of elements.

For example, if the HID points to an allocation of 64 bytes, and the Fixed-size type is a **PtypInteger64** (8 bytes), then the number of items in the MV property is  $64 / 8 = 8$  items. The size of the heap or node data MUST be an integer multiple of the data type size.

#### 2.3.3.4.2 MV Properties with Variable-size Base Type

When the MV property contains variable-size elements, such as **PtypBinary**, **PtypString**, or **PtypString8**, the data layout is more complex. The following is the data format of a multi-valued property with variable-size base type.

Unicode / ANSI:

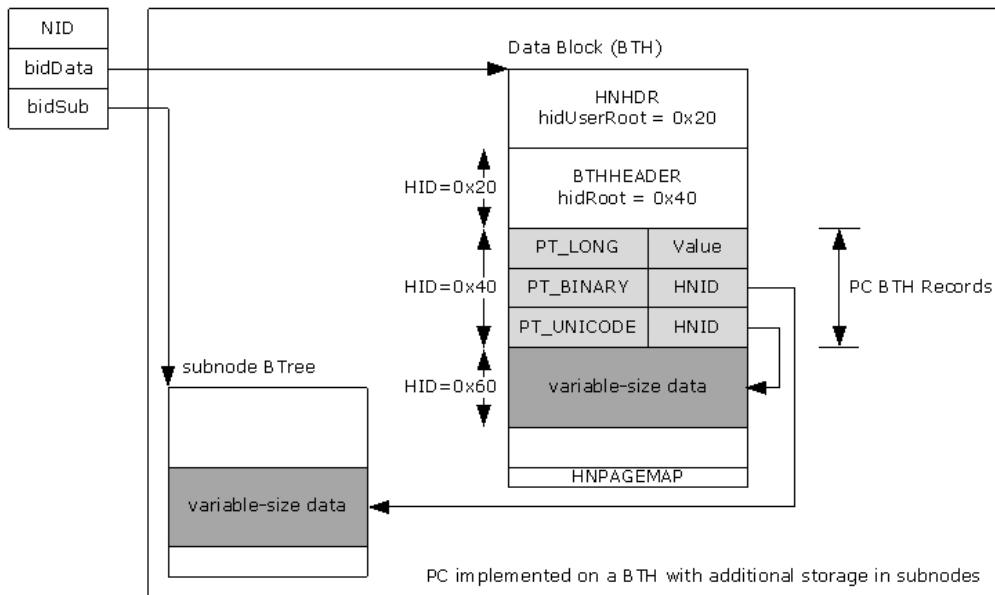

**ulCount (4 bytes):** Number of data items in the array.

**rgulOffsets (variable):** An array of ULONG values that represent offsets to the start of each data item for the MV array. Offsets are relative to the beginning of the MV property data record. The length of the N<sup>th</sup> data item is calculated as: **rgulOffsets[N+1] – rgulOffsets[N]**, with the exception of the last item, in which the total size of the MV property data record is used instead of rgulOffsets[N+1].

**rgDataItems (variable size):** A byte-aligned array of data items. Individual items are delineated using the **rgulOffsets** values.

### 2.3.3.5 Anatomy of a PC

The following diagram provides a visual representation how the various storage scenarios play out in a PC:

**Figure 6: Data Organization of a Property Context**

This example shows a PC that is represented using a single data block and the subnode. For a small BTH, a subnode is not used. The data block points to a HN, which in turn contains a BTH that is built on top of a HN as shown. For a PC, the **hidUserRoot** of the HN points to the BTHHEADER (allocated

form the heap with HID=0x20). The **hidRoot** of the BTHHEADER points to the array of PC BTH records, which is also allocated from the heap (with HID=0x40).

The Property-Value pairs in the PC BTH records are stored using the rules described in the previous sections. For a 32-bit **PtypInteger32** ([MS-OXCDATA] section 2.12.1) property, the value is stored inline. For variable-size properties such as strings and binary BLOBs, an HNID is used to reference the data location. For the **PtypString** ([MS-OXCDATA] section 2.12.1) case, the data fits into the available space in the heap, and therefore is stored in the heap (HNID=0x60).

In the **PtypBinary** ([MS-OXCDATA] section 2.12.1) case, because the BLOB is too large to fit within the heap (larger than 3580 bytes), the subnode is used to store the data. In this case, the value of HNID is set to the subnode NID that contains the binary data. Note that the subnode structure in the diagram is significantly simplified for illustrative purposes.

### 2.3.4 Table Context (TC)

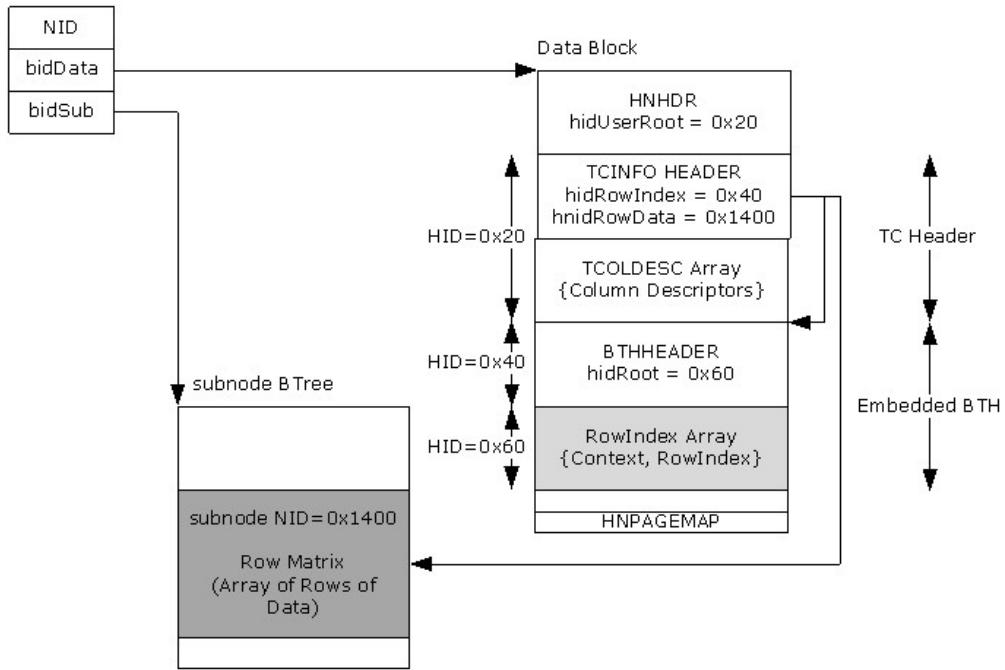

A Table Context represents a table with rows of columns. From an implementation perspective, a TC is a complex, composite structure that is built on top of a HN. The presence of a TC is indicated at both the NDB and LTP Layers. At the NDB Layer, a TC is indicated through one of the special NID\_TYPES, and at the LTP Layer, a value of **bTypeTC** for **bClientSig** in the HNHEADER structure is reserved for TCs. The underlying TC data is separated into 3 entries: a header with Column descriptors, aRowIndex (a nested BTH), and the actual table data (known as the Row Matrix).

The Row Matrix contains the actual row data for the TC. New rows are always appended to the end of the Row Matrix, which means that the rows are not sorted in any meaningful manner. To provide a way to efficiently search the Row Matrix for a particular data row, each TC also contains an embedded BTH, known as theRowIndex, to provide a 32-bit "primary index" for the Row Matrix. Each 32-bit value is a key that uniquely identifies a row within the Row Matrix.

In practice, the Row Matrix is usually stored in a subnode because of its typical size, but in rare cases, a TC can fit into a single data block if it is small enough. To facilitate navigation between rows, each row of data is of the same size, and the size is stored in the TCINFO header structure (section 2.3.4.1). To further help with data packing and alignment, the data values are grouped according to its corresponding data size. DWORD and ULONGLONG values are grouped first, followed by WORD-sized data, and then byte-sized data. The TCINFO structure contains an array of offsets that points to the starting offset of each group of data.

The TC also includes a construct known as a Cell Existence Bitmap (CEB), which is used to denote whether a particular column in a particular row actually "exists". A CEB is present at the end of each row of data in the Row Matrix that indicates which columns in that row exists and which columns don't exist.

The following diagram depicts the various elements of a TC, and how they relate to each other:

**Figure 7: Data Organization of a Table Context**

The preceding example illustrates a typical TC arrangement, where the metadata is stored in the main data block (a data tree can be used if the TC is large), and the RowMatrix is stored in the corresponding subnode. Note that the numerical values used in the example are for reference purposes only.

The **hidUserRoot** of the HNHDR points to the TC header, which is allocated from the heap with HID=0x20. The TC header contains a TCINFO structure, followed by an array of column descriptors. The TCINFO structure contains pointers that point to the RowIndex (**hidRowIndex**) and The Row Matrix (hidrowData). The RowIndex is always allocated off the heap, whereas the Row Matrix is typically stored in the subnode (in rare cases where the TC is very small, the Row Matrix can be stored in a heap allocation instead. Note that the subnode structure in the diagram is significantly simplified for illustrative purposes.

The next sections describe actual data structures associated with Table Contexts:

#### 2.3.4.1 TCINFO

TCINFO is the header structure for the TC. The TCINFO is accessed using the **hidUserRoot** field in the HNHDR structure of the containing HN. The header contains the Column definitions and other relevant data.

Unicode / ANSI:

0	1	2	3	4	5	6	7	8	9	1	0	1	2	3	4	5	6	7	8	9	2	0	1	2	3	4	5	6	7	8	9	3	0	1
bType								cCols								rgib																		

...	...
...	hidRowIndex
...	hnidRows
...	hidIndex
...	rgTCOLDESC (variable)
...	...
...	...
...	...

**bType (1 byte):** TC signature; MUST be set to **bTypeTC**.

**cCols (1 byte):** Column count. This specifies the number of columns in the TC.

**rgib (8 bytes):** This is an array of 4 16-bit values that specify the offsets of various groups of data in the actual row data. The application of this array is specified in section [2.3.4.4](#), which covers the data layout of the Row Matrix. The following table lists the meaning of each value:

Index	Friendly Name	Meaning of rgib[Index] Value
0	TCI_4b	Ending offset of 8- and 4-byte data value group
1	TCI_2b	Ending offset of 2-byte data value group
2	TCI_1b	Ending offset of 1-byte data value group
3	TCI_bm	Ending offset of the Cell Existence Block

**hidRowIndex (4 bytes):** HID to the Row ID BTH. The Row ID BTH contains (RowID, RowIndex) value pairs that correspond to each row of the TC. The RowID is a value that is associated with the row identified by the RowIndex, whose meaning depends on the higher level structure that implements this TC. The RowIndex is the zero-based index to a particular row in the Row Matrix.

**hnidRows (4 bytes):** HNID to the Row Matrix (that is, actual table data). This value is set to zero (0) if the TC contains no rows.

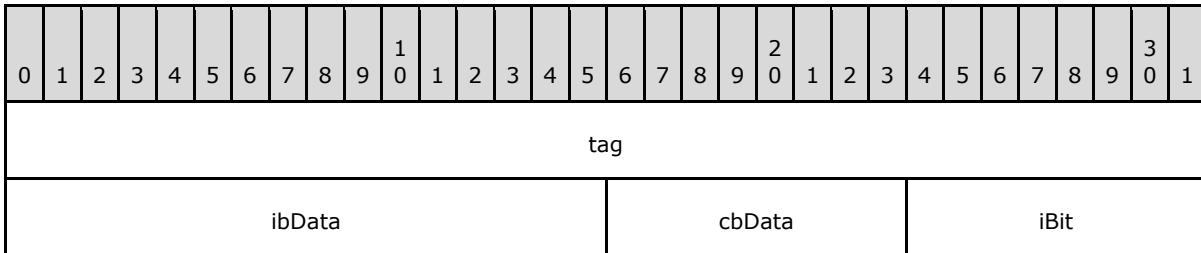

**hidIndex (4 bytes):** Deprecated. Implementations SHOULD ignore this value, and creators of a new PST MUST set this value to zero (0).

**rgTCOLDESC (variable):** Array of Column Descriptors. This array contains **cCol** entries of type **TCOLDESC** structures that define each TC column.

### 2.3.4.2 TCOLDESC

The **TCOLDESC** structure describes a single column in the TC, which includes metadata about the size of the data associated with this column, as well as whether a column exists, and how to locate the column data from the Row Matrix.

Unicode / ANSI:

**tag (4 bytes):** This field specifies that 32-bit tag that is associated with the column.

**ibData (2 bytes):** Data Offset. This field indicates the offset from the beginning of the row data (in the Row Matrix) where the data for this column can be retrieved. Because each data row is laid out the same way in the Row Matrix, the Column data for each row can be found at the same offset.

**cbData (1 byte):** Data size. This field specifies the size of the data associated with this column (that is, "width" of the column), in bytes per row. However, in the case of variable-sized data, this value is set to the size of an HNID instead. This is explained further in section [2.3.4.4](#).

**iBit (1 byte):** Cell Existence Bitmap Index. This value is the 0-based index into the CEB bit that corresponds to this Column.

### 2.3.4.3 TheRowIndex

The **hnidRowID** member in TCINFO points to an embedded BTH that contains an array of (**dwRowID**, **dwRowIndex**) value pairs, which provides a 32-bit primary index for searching the Row Matrix. Simply put, the RowIndex maps **dwRowID**, a unique identifier, to the index of a particular row in the Row Matrix.

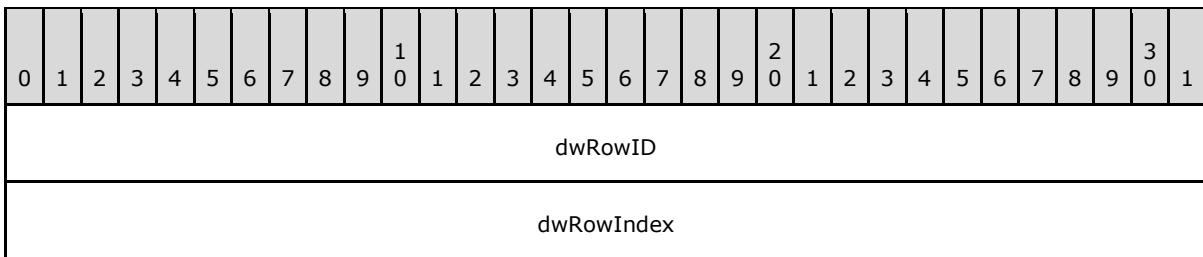

The RowIndex itself is a generic mechanism to provide a 32-bit primary key and therefore it is up to the implementation to decide what value to use for the primary key. However, a NID value is typically used as the primary key because of its uniqueness within a PST.

The following is the layout of the BTH data record used in the RowIndex.

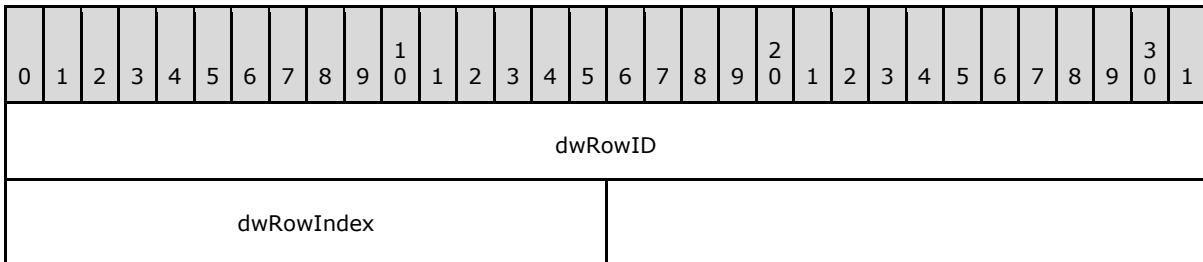

#### 2.3.4.3.1 TCROWID

The TCROWID structure is a manifestation of the BTH data record (section [2.3.2.3](#)). The size of the TCROWID structure varies depending on the version of the PST. For the Unicode PST, each record in the BTH are 8 bytes in size, where cbKey=4 and cEnt=4. For an ANSI PST, each record is 6 bytes in size, where cbKey=4 and cEnt=2. The following is the binary layout of the TCROWID structure.

Unicode:

ANSI:

**dwRowID (4 bytes):** This is the 32-bit primary key value that uniquely identifies a row in the Row Matrix.

**dwRowIndex (Unicode: 4 bytes; ANSI: 2 bytes):** The 0-based index to the corresponding row in the Row Matrix. Note that for ANSI PSTs, the maximum number of rows is  $2^{16}$ .

#### 2.3.4.4 Row Matrix

The Row Matrix contains the actual data for the rows and columns of the TC. The data is physically arranged in rows; each row contains the data for each of its columns. Each row of column data in the Row Matrix is of the same size and is arranged in the same layout, and the size of each row is specified in the **rgib[TCI\_bm]** value in the TCINFO header structure.

However, in many cases, the Row Matrix is larger than 8KB and therefore cannot fit in a single data block, which means that a data tree is used to store the Row Matrix in separate data blocks. This means that the row data is partitioned across two or more data blocks and needs special handling considerations.

The design of a TC dictates that each data block MUST store an integral number of rows, which means that rows cannot span across two blocks, and that each block MUST start with a fresh row. This also means that in order for a client to access a particular row in the Row Matrix, it first calculates how many rows fit in a block, and calculates the row index within that block at which the row data is located. The general formula to calculate the block index and row index for the N<sup>th</sup> row are as follows:

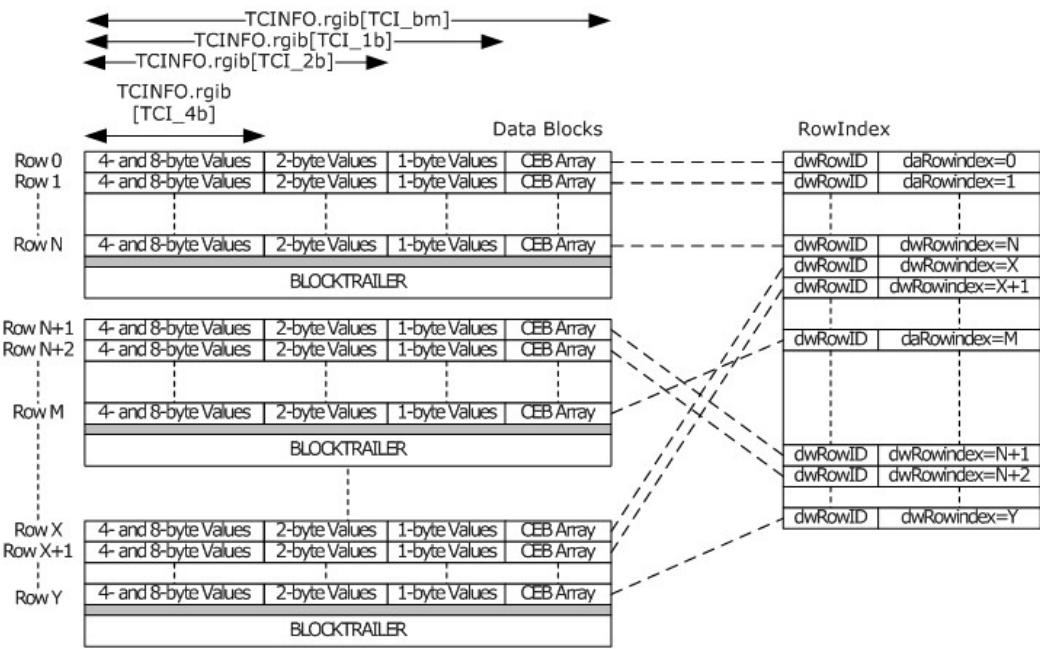

$$\text{RowsPerBlock} = \text{Floor}((\text{sizeof}(block) - \text{sizeof}(BLOCKTRAILER)) / \text{TCINFO.rgib[TCI_bm]})$$

$$\text{BlockIndex} = N / \text{RowsPerBlock}$$

$$\text{RowIndex} = N \% \text{RowsPerBlock}$$

Where `sizeof(block)` is 8192 bytes.

The following diagram illustrates how the data in the Row Matrix is organized.

**Figure 8: Data Organization of the Row Matrix**

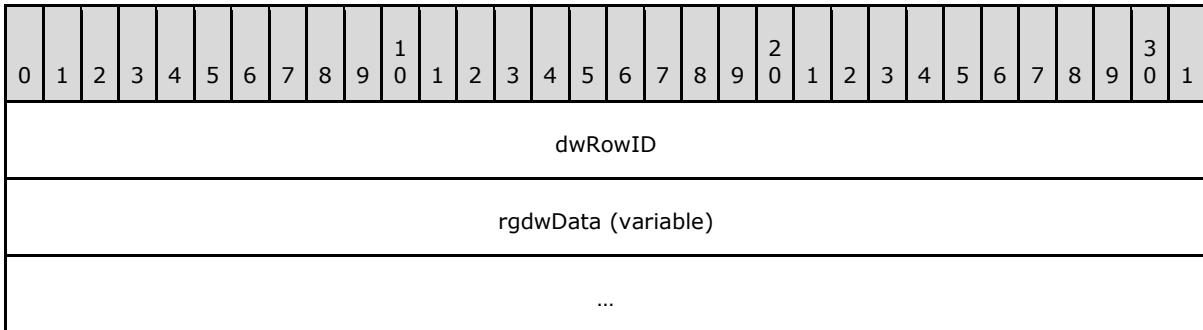

In addition to showing the data organization of the Row Matrix, this diagram also illustrates how the rows in the RowIndex relate to the row data in the Row Matrix. As illustrated by the crossing of dotted lines between the two structures, the Row Matrix data is unsorted, which makes searching inefficient. The RowIndex, which is implemented using an embedded BTH indexed by **dwRowID**, provides the primary search key to lookup specific rows in the Row Matrix.

It is also worth noting that because of the fact that partial rows are not allowed, there might be unused space at the end of the data block (shaded in gray in the diagram). Readers MUST ignore any such "dead space" and MUST NOT interpret its contents.

#### 2.3.4.4.1 Row Data Format

The following is the organization of a single row of data in the Row Matrix. Rows of data are tightly-packed in the Row Matrix, and the size of each data row is **TCINFO.rgib[TCI\_bm]** bytes.

Unicode / ANSI:

rgwData (variable)
...
rgbData (variable)
...
rgbCEB (variable)
...

**dwRowID (4 bytes):** The 32-bit value that corresponds to the **dwRowID** value in this row's corresponding TCROWID record. Note that this value corresponds to the **PidTagLtpRowId** property.

**rgdwData (variable size):** 4-byte-aligned Column data. This region contains data with a size that is a multiple of 4 bytes. The types of data stored in this region are 4-byte and 8-byte values.

**rgwData (variable size):** 2-byte-aligned Column data. This region contains data that are 2 bytes in size.

**rgbData (variable size):** Byte-aligned Column data. This region contains data that are byte-sized.

**rgbCEB (variable size):** Cell Existence Block. This array of bits comprises the CEB, in which each bit corresponds to a particular Column in the current row. The mapping between CEB bits and actual Columns is based on the **iBit** member of each **TCOLDESC**, where the bit in the CEB at the offset indicated by the **iBit** indicates whether the particular column exists. The size of **rgCEB** is  $\text{Ceil}(\text{TCINFO.cCols} / 8)$  bytes. Extra high-order bits SHOULD be ignored. Creators of a new PST MUST set the extra high-order bits to zero (0).

#### 2.3.4.4.2 Variable-sized Data

With respect to the TC, variable-sized data is defined as any data type that allows a variable size (such as strings), or any fixed-size data type that exceeds 8 bytes (for example, a GUID). In the case of variable-sized data, the actual data is stored elsewhere in the heap or in a subnode, and the HNID that references the data is stored the corresponding **rgdwData** slot instead. The following is a list of the property types that are stored using an HNID. A complete list of property types is specified in [\[MS-OXCDATA\]](#) section 2.12.1.

- **PtypString**
- **PtypString8**
- **PtypBinary**
- **PtypObject**
- **PtypGuid**
- All multi-valued types

The following table illustrates the handling of fixed- and variable-sized data in the TC (see section [2.3.3.2](#) for determining if an HNID is a HID or a NID).

<b>Variable Size?</b>	<b>Fixed Data Size</b>	<b>NID_TYPE(dwValueHnid) == NID_TYPE_HID?</b>	<b>rgdwData Value</b>
N	<= 8 bytes*	-	Data Value
	> 8 bytes*	Y	HID
Y	-	Y	HID (<= 3580 bytes)
		N	NID (subnode, > 3580 bytes)

Note: this contrasts with the PC in that the TC stores 8-byte values inline (in **rgdwData**), whereas a PC would use an HNID for any data that exceeds 4-bytes in size.

#### 2.3.4.4.3 Cell Existence Test

Despite the existence of the CEB, the size of each row of column data is still the same for every row. This means that a data slot always exists for a column, whether or not the column exists for that row. Because the data slot of a non-existent column contains random values, third-party implementations MUST first check the CEB to determine if a column exists, and only process the column data if the column exists. This prevents any confusion resulting from interpreting invalid data from non-existent columns. Implementations MUST set the value of a non-existent column to zero (0).

### 2.4 Messaging Layer

The Messaging Layer is a high-level Layer that exposes functionality provided in the LTP Layer through Messaging semantics. Instead of primitive Property and Table Contexts, the Messaging Layer exposes objects in terms of Message store, Folder objects, Message objects and Attachment objects, and defines the composite structures for each of these objects, as well as defines the rules that interrelate these objects with each other.

#### 2.4.1 Special Internal NIDs

This section focuses on a special NID\_TYPE: NID\_TYPE\_INTERNAL (0x01). As specified in section [2.2.2.1](#), the **nidType** of a NID is ignored by the NDB Layer, and is left for the interpretation by higher level implementations.

In the Messaging Layer, nodes with various **nidType** values are also used to build related structures that collectively represent complex structures (for example, a Folder object is a composite object that consists of a PC and three TCs of various **nidType** values). In addition, the Messaging Layer also uses NID\_TYPE\_INTERNAL to define special NIDs that have special functions.

Because top-level NIDs are globally-unique within a PST, it follows that each instance of a special NID can only appear once in a PST. The following is a list of all pre-defined internal NIDs.

<b>Value</b>	<b>Friendly Name</b>	<b>Meaning</b>
0x21	NID_MESSAGE_STORE	Message store node (section <a href="#">2.4.3</a> )
0x61	NID_NAME_TO_ID_MAP	Named Properties Map (section <a href="#">2.4.7</a> )

Value	Friendly Name	Meaning
0xA1	NID_NORMAL_FOLDER_TEMPLATE	Special template node for an empty Folder object
0xC1	NID_SEARCH_FOLDER_TEMPLATE	Special template node for an empty search Folder object
0x122	NID_ROOT_FOLDER	Root Mailbox Folder object of PST
0x1E1	NID_SEARCH_MANAGEMENT_QUEUE	Queue of Pending Search-related updates
0x201	NID_SEARCH_ACTIVITY_LIST	Folder object NIDs with active Search activity
0x241	NID_RESERVED1	Reserved
0x261	NID_SEARCH_DOMAIN_OBJECT	Global list of all Folder objects that are referenced by any Folder object's Search Criteria
0x281	NID_SEARCH_GATHERER_QUEUE	Search Gatherer Queue (section <a href="#">2.4.8.5.1</a> )
0x2A1	NID_SEARCH_GATHERER_DESCRIPTOR	Search Gatherer Descriptor (section <a href="#">2.4.8.5.2</a> )
0x2E1	NID_RESERVED2	Reserved
0x301	NID_RESERVED3	Reserved
0x321	NID_SEARCH_GATHERER_FOLDER_QUEUE	Search Gatherer Folder Queue (section <a href="#">2.4.8.5.3</a> )

## 2.4.2 Properties

A property is the basic unit of information in the Messaging Layer. Each property consists of a property tag, and a Value. The property tag consists of a property identifier, which identifies the property, and a property type, which identifies the type of data associated with the property.

### 2.4.2.1 Standard Properties

This document assumes the reader is already familiar with the concept of properties, and does not delve into details about properties beyond what is required to describe how properties are stored and handled in the PST file format. Property definitions are specified in [\[MS-OXPROPS\]](#).

### 2.4.2.2 Named Properties

**Named properties** are a special type of properties which reside in a reserved range of property identifier values (that is, WORD values between 0x8000 and 0x8FFF). Named properties, unlike standard properties, have names and meanings that are context-specific.

The assignment of named property property identifiers is always sequential and starts from 0x8000. The first named property in the Message store always has a property identifier of 0x8000, followed by 0x8001, and so on. A mapping exists to map these property identifiers to property names. Note that a named property only maps a property identifier to a property name (which is a (GUID, Value) pair), but it says nothing about the data type of the named property. The data type of the named property is specified in property tag when the property is actually used (or stored). The effective scope of named properties is limited to the current PST only. In other words, the same named property identifier (for example, 0x8003) might map to different properties in different PSTs.

There are two ways to map a named property identifier (NPID) to a property name, the first way is to associate the NPID to a (GUID, string) value pair, and the second way is to associate the NPID to

a (GUID, NameID) value pair. Each PST contains a special construct to provide the mapping between NPIDs to their property names. The technical details of this mapping mechanism are quite involved, and is presented in section [2.4.7](#).

### 2.4.2.3 Calculated Properties

Calculated properties are properties that are well-known to the public but are not physically stored in the PST as individual properties. Instead, these properties are derived or calculated in one way or another using other properties and/or other existing data. A detailed account of all the calculated properties and how they are evaluated can be found in section [2.5](#).

### 2.4.3 Message store

At the PST level, the Message store is the root of the PST, which is the rough equivalent of the top of a Mailbox. The Message store contains the top-level PST settings and metadata that are required to access and manage the PST contents.

At the LTP Level, the Message store implemented as a regular PC. At the NDB Layer, the Message store is identified with a special internal NID value of NID\_MESSAGE\_STORE (0x21) (see section 2.3.1). Any valid PST MUST have exactly one Message store node.

#### 2.4.3.1 Minimum Set of Required Properties

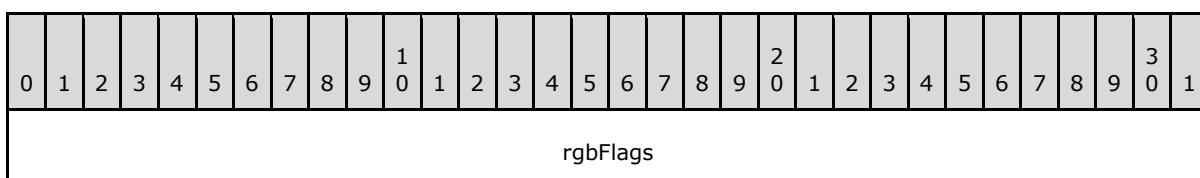

The following properties MUST be present in any valid Message store PC.

Property Identifier	Property Type	Friendly Name	Description
0x0FF9	PtypBinary	<b>PidTagRecordKey</b>	Record Key. This is the Provider UID of this PST.
0x3001	PtypString	<b>PidTagDisplayNameW</b>	Display Name of PST
0x35E0	PtypBinary	<b>PidTagIpmSuBTreeEntryId</b>	EntryID of the Root Mailbox Folder object
0x35E3	PtypBinary	<b>PidTagIpmWastebasketEntryId</b>	EntryID of the Deleted Items Folder object
0x35E7	PtypBinary	<b>PidTagFinderEntryId</b>	EntryID of the search Folder object

#### 2.4.3.2 Mapping between EntryID and NID

Objects in the Message store are accessed externally using EntryIDs ([\[MS-OXCDATA\]](#) section 2.2), where within the PST, objects are accessed using their respective NIDs. The following explains the layout of the ENTRYID structure, which is used to map between a NID and its EntryID:

Unicode / ANSI:

uid (16 bytes)
nid

**rgbFlags (4 bytes):** Flags; each of these bytes MUST be initialized to zero (0).

**uid (16 bytes):** The provider UID of this PST, which is the value of the **PidTagRecordKey** property in the Message store. If this property does not exist, the PST client MAY generate a new unique ID, or reject the PST as invalid.

**nid (4 bytes):** This is the corresponding NID of the underlying node that represents the object.

The corresponding NID of an EntryID can be directly extracted from the EntryID structure. In addition, the NID\_TYPE of the NID can be further verified to ensure that the type of node (for example, NID\_TYPE\_NORMAL\_MESSAGE) actually matches the type of object being referenced. Also, as a further verification mechanism, implementations can compare the **uid** field against the **PidTagRecordKey** property in the Message store to ensure the EntryID actually refers to an item in the current PST. This is particularly useful if the implementation supports opening more than one PST at a time.

Conversely, the procedure for converting a NID to an EntryID simply involves constructing the ENTRYID structure from the NID and the PST Provider UID (**PidTagRecordKey**).

#### 2.4.3.3 PST Password Security

PST files support a password-protect feature that requires an end user to enter a pre-defined password before the PST can be opened. In practice, the PST password is just implemented at the UI level, meaning that the password is only required to gain access of the PST through the UI. The password itself is not used to secure the PST data in any way.

Specifically, the CRC-32 hash of the password text is stored in the **PidTagPstPassword** property in the PC associated with NID\_MESSAGE\_STORE, and if the property exists and is nonzero, implementations SHOULD prompt the end user for a password, compute the CRC-32 hash of the user password, and verify it against the value stored in **PidTagPstPassword**. Implementations MUST enforce the PST Password check if a nonzero value for **PidTagPstPassword** is set in the Message store. Further discussion on PST Password Security can be found in section [4.2](#).

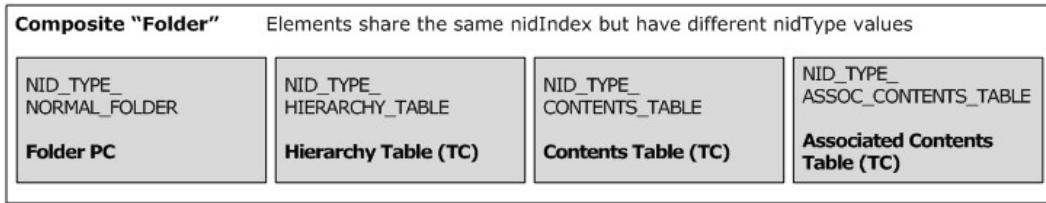

#### 2.4.4 Folders

Folder objects are hierarchical containers that are used to create a storage hierarchy for the Message store. In the PST architecture, a single root Folder object exists at the top of the Message store, from which an arbitrarily complex hierarchy of Folder objects descends to provide structured storage for all the Messaging Objects.

At the LTP level, a Folder object is a composite entity that is represented using four LTP constructs. Specifically, each Folder object consists of one PC, which contains the properties directly associated with the Folder object, and three TCs for information about the contents, hierarchy and other associated information of the Folder object. Some Folder objects MAY have additional nodes that pertain to Search, which is discussed in section [2.4.8.6](#).

At the NDB level, the 4 LTP constructs are persisted as 4 separate top-level nodes (that is, 4 different NIDs). For identification purposes, the **nidIndex** portion for each of the NIDs is the same to indicate that these nodes collectively make up a Folder object. However, each of the 4 NIDs has a

different **nidType** value to differentiate their respective function. The following diagram indicates the relationships among these elements.

**Figure 9: Components of a Folder object**

The following sections explain the structure and function of each of the 4 composite elements of a Folder object,

#### 2.4.4.1 Folder object PC

The Folder object PC is a PC that contains the immediate properties of the Folder object. The NID of a Folder object PC MUST have a NID\_TYPE of NID\_TYPE\_NORMAL\_FOLDER.

##### 2.4.4.1.1 Property Schema of a Folder object PC

The default property schema of a Folder object is specified in [\[MS-OXCFOLD\]](#) and [\[MS-OXPROPS\]](#). However, the following properties MUST be present in any valid Folder object PC.

Property Identifier	Property Type	Friendly Name	Description
0x3001	PtypString	PidTagDisplayNameW	Display name of the Folder object
0x3602	PtypInteger32	PidTagContentCount	Total number of items in the Folder object
0x3603	PtypInteger32	PidTagContentUnreadCount	Number of unread items in the Folder object
0x360A	PtypBoolean	PidTagSubfolders	Whether the Folder object has any sub-Folder objects

##### 2.4.4.1.2 Locating the Parent Folder object

The **nidParent** member in a Folder object PC node contains the NID of its parent Folder object. This allows efficient recursive traversal of parent Folder objects by only accessing the Folder object PC node of each Folder object.

#### 2.4.4.2 Folder Template Tables

The PST has the notion of folder template tables, which are blank TCs (that is, no data rows) with a set of columns. A folder template table exists for each of the three Folder object TCs (Hierarchy, Contents and folder associated information (FAI)), and the folder template table serves two purposes:

- Defines the default column schema for each Folder object TC, and
- Specifies which columns to copy from the child object into the TC.

In the first case, whenever a new Folder object is created, each of the folder template table TCs is duplicated into the new Folder object, which defines the default set of columns for each of the Folder object TCs. For the second case, when a new child object is created under the Folder object (for example, sub-Folder object, Message object, and so on), the default columns determine which properties of the child object is to be copied into the appropriate TC row.

#### 2.4.4.3 Data Duplication and Coherency Maintenance

It follows from the previous sections that information in each row of the Folder object TC are duplicates of properties in a child object. While this duplication of information allows efficient enumeration of sub-objects without having to enumerate and examine the sub-object nodes one-by-one, this duplication of information also requires additional effort to keep both copies of the information in sync. Implementations MUST ensure that changes to the underlying child object are correctly reflected in the appropriate parent Folder object TC.

#### 2.4.4.4 Hierarchy Table

The hierarchy table is implemented as a TC. The NID of a hierarchy table MUST have a NID\_TYPE of NID\_TYPE\_HIERARCHY\_TABLE. Its function is to list the immediate sub-Folder objects of the Folder object. Note that the hierarchy table only contains sub-Folder object information. Information about Message objects stored in the Folder object is stored in the Contents Table (section 2.4.4.5) instead.

##### 2.4.4.4.1 Hierarchy Table Template

Each PST MUST have one hierarchy table template, which is identified with a NID value of NID\_HIERARCHY\_TABLE\_TEMPLATE (0x60D). The hierarchy table template defines the set of columns for every new hierarchy table that is created. The hierarchy table template MUST have no data rows, and MUST contain the following property columns.

Property Identifier	Property Type	Friendly Name	Description	Copied?
0x00E3	PtypInteger32	<b>PidTagReplItemId</b>	Replication Item ID	N
0x0E33	PtypInteger64	<b>PidTagReplChangenum</b>	Replication Change Number	N
0x0E34	PtypBinary	<b>PidTagReplVersionHistory</b>	Replication Version History	N
0x0E38	PtypInteger32	<b>PidTagReplFlags</b>	Replication flags	Y
0x3001	PtypString	<b>PidTagDisplayNameW</b>	Display name of sub-Folder object	Y
0x3602	PtypInteger32	<b>PidTagContentCount</b>	Total number of items in the Folder object	Y
0x3603	PtypInteger32	<b>PidTagContentUnreadCount</b>	Number of unread items in the Folder object	Y
0x360A	PtypBoolean	<b>PidTagSubfolders</b>	Whether the Folder object has any sub-Folder objects	Y
0x3613	PtypBinary	<b>PidTagContainerClass</b>	Container class of the sub-Folder object	Y

<b>Property Identifier</b>	<b>Property Type</b>	<b>Friendly Name</b>	<b>Description</b>	<b>Copied?</b>
0x6635	<b>PtypInteger32</b>	<b>PidTagPstHiddenCount</b>	Total number of hidden Items in sub-Folder object	Y
0x6636	<b>PtypInteger32</b>	<b>PidTagPstHiddenUnread</b>	Unread hidden items in sub-Folder object	Y
0x67F2	<b>PtypInteger32</b>	<b>PidTagLtpRowId</b>	LTP Row ID	Y
0x67F3	<b>PtypInteger32</b>	<b>PidTagLtpRowVer</b>	LTP Row Version	Y

The right-most column indicates whether the property is copied from the child Folder object PC into the hierarchy TC row when a new child Folder object is created.

#### 2.4.4.4.2 Locating sub-Folder object Nodes

TheRowIndex (section 2.3.4.3) of the hierarchy table TC provides a mechanism for efficiently locating immediate sub-Folder objects. The **dwRowIndex** field represents the 0-based sub-Folder object row in the Row Matrix, whereas the **dwRowID** value represents the NID of the sub-Folder object node that corresponds to the row specified byRowIndex. For example, if a TCROWID is: { **dwRowID=0x8022**, **dwRowIndex=3** }, then the sub-Folder object NID that corresponds to the fourth (first being 0<sup>th</sup>) sub-Folder object row in the Row Matrix is 0x8022.

#### 2.4.4.5 Contents Table

The contents table is a TC node that is identified with a NID\_TYPE of NID\_TYPE\_CONTENTS\_TABLE. Its function is to list the Message objects in the Folder object.

##### 2.4.4.5.1 Contents Table Template

Each PST MUST have one contents table template, which is identified with a NID value of NID\_CONTENTS\_TABLE\_TEMPLATE (0x60E). The contents table template MUST have no data rows, and MUST contain the following property columns.

<b>Property Identifier</b>	<b>Property Type</b>	<b>Friendly Name</b>	<b>Description</b>	<b>Copied?</b>
0x0017	<b>PtypInteger32</b>	<b>PidTagImportance</b>	Importance	Y
0x001A	<b>PtypString</b>	<b>PidTagMessageClassW</b>	Message class	Y
0x0036	<b>PtypInteger32</b>	<b>PidTagSensitivity</b>	Sensitivity	Y
0x0037	<b>PtypString</b>	<b>PidTagSubjectW</b>	Subject	Y
0x0039	<b>PtypTime</b>	<b>PidTagClientSubmitTime</b>	Submit timestamp	Y
0x0042	<b>PtypString</b>	<b>PidTagSentRepresentingNameW</b>	Sender representative name	Y
0x0057	<b>PtypBoolean</b>	<b>PidTagMessageToMe</b>	Whether recipient is in	Y

<b>Property Identifier</b>	<b>Property Type</b>	<b>Friendly Name</b>	<b>Description</b>	<b>Copied?</b>
			To: line	
0x0058	<b>PtypBoolean</b>	<b>PidTagMessageCcMe</b>	Whether recipient is in Cc: line	Y
0x0070	<b>PtypString</b>	<b>PidTagConversationTopicW</b>	Conversation topic	Y
0x0071	<b>PtypBinary</b>	<b>PidTagConversationIndex</b>	Conversation index	Y
0xE03	<b>PtypString</b>	<b>PidTagDisplayCcW</b>	Cc: line	Y
0xE04	<b>PtypString</b>	<b>PidTagDisplayToW</b>	To: line	Y
0xE06	<b>PtypTime</b>	<b>PidTagMessageDeliveryTime</b>	Message delivery timestamp	Y
0xE07	<b>PtypInteger32</b>	<b>PidTagMessageFlags</b>	Message flags	Y
0xE08	<b>PtypInteger32</b>	<b>PidTagMessageSize</b>	Message size	Y
0xE17	<b>PtypInteger32</b>	<b>PidTagMessageStatus</b>	Message status	Y
0xE30	<b>PtypInteger32</b>	<b>PidTagReplItemid</b>	Replication item ID	Y
0xE33	<b>PtypInteger64</b>	<b>PidTagReplChangenum</b>	Replication change number	Y
0xE34	<b>PtypBinary</b>	<b>PidTagReplVersionHistory</b>	Replication version history	Y
0xE38	<b>PtypInteger32</b>	<b>PidTagReplFlags</b>	Replication flags	Y
0xE3C	<b>PtypBinary</b>	<b>PidTagReplCopiedfromVersionhistory</b>	Replication version information	Y
0xE3D	<b>PtypBinary</b>	<b>PidTagReplCopiedfromitemid</b>	Replication item ID information	Y
0x1097	<b>PtypInteger32</b>	<b>PidTagItemTemporaryFlags</b>	Temporary flags	Y
0x3008	<b>PtypTime</b>	<b>PidTagLastModificationTime</b>	Last modification time of Message object	Y
0x65C6	<b>PtypInteger32</b>	<b>PidTagSecureSubmitFlags</b>	Secure submit flags	Y
0x67F2	<b>PtypInteger32</b>	<b>PidTagLtpRowId</b>	LTP row ID	Y

Property Identifier	Property Type	Friendly Name	Description	Copied?
0x67F3	PtypInteger32	PidTagLtpRowVer	LTP row version	Y

The right-most column indicates whether the property is copied from the Message object PC into the Contents TC row when a new Message object is created.

#### 2.4.4.5.2 Locating Message object Nodes

TheRowIndex (section 2.3.4.3) of the contents table TC provides an efficient mechanism to locate the Message object PC node of every Message object in the Folder object. The **dwRowIndex** field represents the 0-based Message object row in the Row Matrix, whereas the **dwRowID** value represents the NID of the Message object node that corresponds to the row specified byRowIndex. For example, if a TCROWID is: { **dwRowID**=0x200024, **dwRowIndex**=3 }, then the NID that corresponds to the fourth (first being 0<sup>th</sup>) Message object row in the Row Matrix is 0x200024.

#### 2.4.4.6 FAI contents table

The FAI contents table is a TC node identified with a NID\_TYPE of NID\_TYPE\_ASSOC\_CONTENTS\_TABLE. Its function is to list the FAI Message objects in the Folder object.

##### 2.4.4.6.1 FAI contents table Template

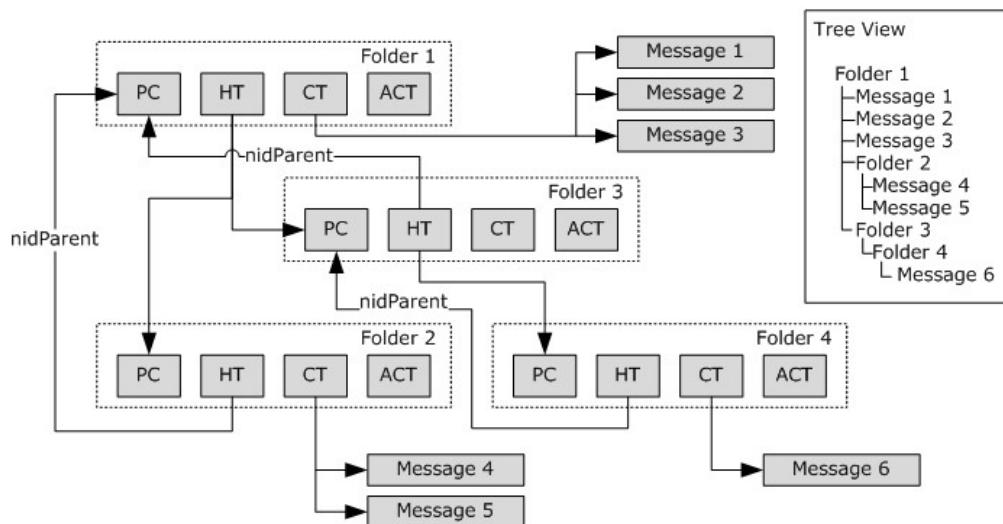

Each PST MUST have one FAI contents table template, which is identified with a NID value of NID\_ASSOC\_CONTENTS\_TABLE\_TEMPLATE (0x60F). The FAI contents table template MUST have no data rows, and MUST contain the following property columns.

Property Identifier	Property Type	Friendly Name	Description	Copied?
0x001A	PtypString	PidTagMessageClassW	Message class	Y
0x0E07	PtypInteger32	PidTagMessageFlags	Message flags	Y
0x0E17	PtypInteger32	PidTagMessageStatus	Message status	Y
0x3001	PtypString	PidTagDisplayNameW	Display name	Y
0x67F2	PtypInteger32	PidTagLtpRowId	LTP row ID	Y
0x67F3	PtypInteger32	PidTagLtpRowVer	LTP row version	Y
0x6800	PtypString	PidTagOfflineAddressBookNameW	OAB name	Y
0x6803	PtypBoolean	PidTagSendOutlookRecallReport	Send recall report	Y
0x6805	PtypMultipleInteger	PidTagOfflineAddressBookTruncatedProp	OAB	Y

Property Identifier	Property Type	Friendly Name	Description	Copied?
	32	erties	truncated props	
0x682F	PtypString	PidTagMapiFormComposeCommand		Y
0x7003	PtypInteger32	PidTagViewDescriptorFlags	View descriptor flags	Y
0x7004	PtypBinary	PidTagViewDescriptorLinkTo	View descriptor link	Y
0x7005	PtypBinary	PidTagViewDescriptorViewFolder	View descriptor Folder object	Y
0x7006	PtypString	PidTagViewDescriptorName	View descriptor name	Y
0x7007	PtypInteger32	PidTagViewDescriptorVersion	View descriptor version	Y

#### 2.4.4.7 Anatomy of a Folder Hierarchy

The following diagram links all the Folder object concepts together by illustrating how each element interrelates with each other.

**Figure 10: Anatomy of a Folder Hierarchy**

The preceding example illustrates how the various elements of a Folder object work together to represent a Folder object hierarchy. The equivalent "tree view" of the hierarchy is indicated on the right.

At the top of the hierarchy is Folder object 1, which contains 3 Message objects and 2 sub-Folder objects. The PC contains all the properties associated with Folder object 1, where the hierarchy table (HT) contains information about the 2 sub-Folder objects: Folder object 2 and Folder object 3. The information about the 3 Message objects in the Folder object, however, is stored in the contents table (CT). While not shown, the FAI contents table contains FAI Message objects that pertain to Folder object 1. For more information about FAI Message objects, see [MS-OXCMSG] section 1.3.2. In addition, the RowIndex of Folder object 1's HT contains the necessary NID mappings that enable navigation from Folder object 1 to Folder objects 2 and 3. The relationship applies recursively to Folder object 2 and Folder object 3, and eventually, to Folder object 4, as shown in the preceding diagram.

Note the use of the **nidParent** field in the hierarchy table node to point back to the NID of the parent Folder object. Also note that all arrows eventually point to the Folder object PC node, whose NID can be replaced with different NID\_TYPES to access the other TCs.

#### 2.4.4.8 Implications of Modifying a Folder Template Table

Modifying the list of columns in a folder template table TC impacts the column list of the corresponding Folder object TC for Folder objects created subsequent to the modification. The modification SHOULD NOT impact Folder objects that were created prior to the modification. Implementations MUST NOT remove columns from a template Table that is part of its original template Table definition.

Implementations MUST NOT create data rows in a folder template table.

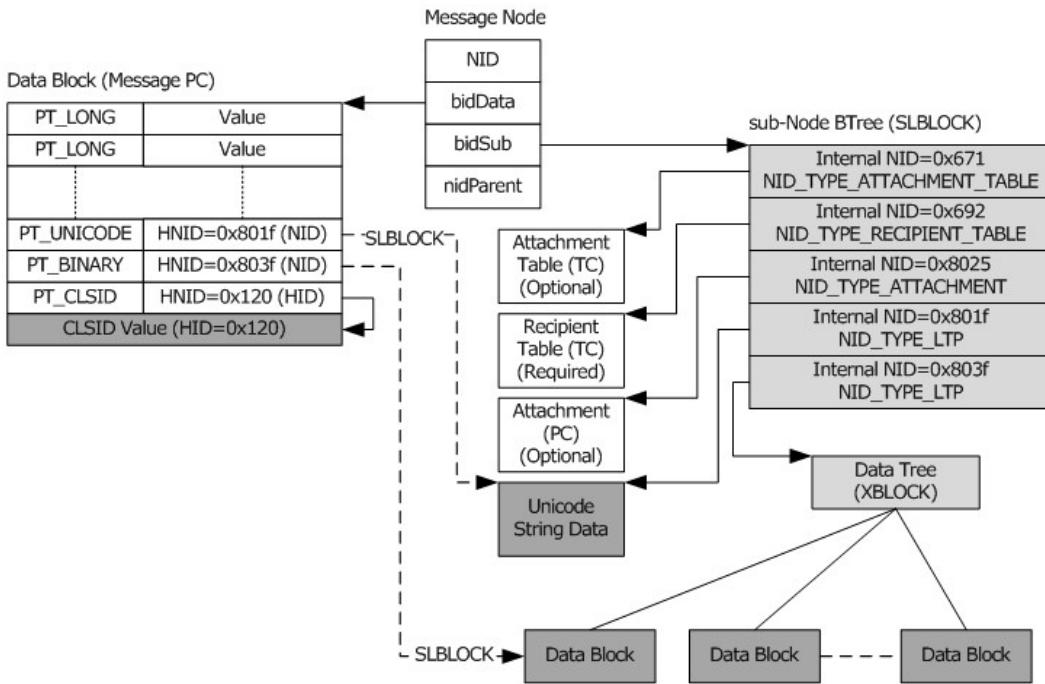

#### 2.4.4.9 Implications of Modifying a Folder object TC

In general, columns can be added to existing Folder object TCs. Any new columns added to a Folder object TC MUST also be copied from the child object, if the property exists in the child object, otherwise, the new column is marked as non-existent for that particular row. Implementations MUST also make sure that the information in the TC are kept in sync with the underlying child objects.

Implementations MUST NOT remove columns form a TC (that is, remove a TCOLDEF).

### 2.4.5 Message objects

A Message object is a composite structure, but unlike a Folder object, all the data of a Message object is contained in a single top-level node (that is, accessed through a single top-level NID). Both the data block and subnode are always used in a Message object node, where the data block contains a PC structure that contains the immediate properties of the Message object, and the subnode contains a number of composite structures that contain information such as the Recipient List and Attachment objects, if any.

**Figure 11: Components of a Message object**

The preceding diagram is an illustration of the various components of a Message object node. The data block contains the Message object PC, which contains the properties associated with this Message object. The subnode of the Message object can contain a number of objects, such as: a Recipient Table TC, an optional Attachment Table TC, optional Attachment object PCs, as well as variable-size data from the Message object PC that cannot fit directly into the Message object PC heap. The subnode BTREE contains an array of subnodes that are identified using internal NIDs (that is, unique within the Message object node only). The contents of each subnode are identified primarily by the NID\_TYPE. The following table lists the NID\_TYPES that can be found in the subnode of a Message object node.

NID_TYPE	Description	Required?
NID_TYPE_RECIPIENT_TABLE	The subnode is a Message Recipient Table	Y
NID_TYPE_ATTACHMENT_TABLE	The subnode is an Attachment Table (optional)	N
NID_TYPE_ATTACHMENT	The subnode is an Attachment object	N
NID_TYPE_LTP	The subnode contains raw LTP data for the Message PC	N

#### 2.4.5.1 Message object PC

The Message object PC is a standard Property Context structure that contains the properties associated with the Message object. Message object PC nodes are identified with a NID\_TYPE of NID\_TYPE\_NORMAL\_MESSAGE.

#### 2.4.5.1.1 Property Schema of a Message object PC

Message objects have a rather complicated set of schemas and are out of the scope of discussion of this document. However, the basic property schema of a general Message object is specified in [\[MS-OXCMMSG\]](#), [\[MS-OXOMSG\]](#) and [\[MS-OXPROPS\]](#). From the PST perspective, the following properties MUST be present in any valid Message object PC.

Property Identifier	Property Type	Friendly Name	Description
0x001A	PtypString	<b>PidTagMessageClassW</b>	Message class
0x0E07	PtypInteger32	<b>PidTagMessageFlags</b>	Message flags
0x0E08	PtypInteger32	<b>PidTagMessageSize</b>	Message size
0x0E17	PtypInteger32	<b>PidTagMessageStatus</b>	Message status
0x3007	PtypTime	<b>PidTagCreationTime</b>	Creation time
0x3008	PtypTime	<b>PidTagLastModificationTime</b>	Last modification time
0x300B	PtypBinary	<b>PidTagSearchKey</b>	Message Search Key

#### 2.4.5.2 Locating the Parent Folder object of a Message object

Message objects are not stand-alone entities and therefore each Message object belongs to a parent Folder object. Similar to Folder objects, the **nidParent** member of the Message object node (see the diagram in section 2.4.6.3) contains the NID of the immediate parent Folder object PC of the Message object. This allows efficient moving of Message objects from one Folder object to another simply by updating the **nidParent** to point to the new parent.

#### 2.4.5.3 Recipient Table

The Recipient Table is a standard Table Context structure that is identified with a NID\_TYPE of NID\_TYPE\_RECIPIENT\_TABLE. With the exception of the recipient table template a Recipient Table always resides in the subnode of a Message object node. It contains the list of Recipients of the Message object (one row per Recipient). A Recipient Table MUST exist for any Message object.

##### 2.4.5.3.1 Recipient Table Template

Each PST MUST have one recipient table template, which is identified with a NID value of NID\_RECIPIENT\_TABLE (0x692). The recipient table template defines the set of columns for every new Recipient Table that is created. The recipient table template MUST have no data rows, and MUST contain the following property columns.

Property Identifier	Property Type	Friendly Name	Description
0x0c15	PtypInteger32	<b>PidTagRecipientType</b>	Type of recipient
0x0EOF	PtypBoolean	<b>PidTagResponsibility</b>	Handling Responsibility
0x0FF9	PtypBinary	<b>PidTagRecordKey</b>	Record Key
0x0FFE	PtypInteger32	<b>PidTagObjectType</b>	Recipient Object type
0x0FFF	PtypBinary	<b>PidTagEntryID</b>	EntryID of the recipient

Property Identifier	Property Type	Friendly Name	Description
0x3001	PtypString	<b>PidTagDisplayNameW</b>	Display name of the recipient
0x3002	PtypString	<b>PidTagAddressTypeW</b>	Type of recipient address
0x3003	PtypString	<b>PidTagEmailAddressW</b>	E-mail address of recipient
0x300B	PtypBinary	<b>PidTagSearchKey</b>	Search Key
0x3900	PtypInteger32	<b>PidTagDisplayType</b>	Display type
0x39FF	PtypString	<b>PidTag7BitDisplayNameW</b>	7-bit Display name
0x3A40	PtypBoolean	<b>PidTagSendRichInfo</b>	Send Rich info for recipient
0x67F2	PtypInteger32	<b>PidTagLtpRowId</b>	LTP Row ID
0x67F3	PtypInteger32	<b>PidTagLtpRowVer</b>	LTP Row Version

#### 2.4.5.3.2 Message object Recipient Tables

Recipient Tables in actual Message objects contain all the columns in the recipient table template, plus a number of extra properties about its Recipients. Recipient properties are specified in [\[MS-OXPROPS\]](#).

#### 2.4.6 Attachment objects

An Attachment object is an arbitrary binary object that can be associated with (that is, attached to) a Message object. As illustrated in the diagram in section [2.4.6.3](#), Attachment objects are stored in the subnode of a Message object node, and are therefore only accessible through the Message object node.

A Message object keeps track of its Attachment objects using an optional Attachment Table in its subnode. The Attachment Table is said to be optional because it only exists if a Message object has at least one Attachment object. The presence of Attachment objects is indicated in **PidTagMessageFlags** property in the Message object. The presence of Attachment objects is indicated by the MSGFLAG\_HASATTACH (0x10) bit set to "1" in **PidTagMessageFlags**. If Attachment objects are present, then the Attachment Table can be accessed by scanning the subnode BTREE of the Message object subnode to locate a subnode whose NID is NID\_ATTACHMENT\_TABLE. Each Message object MUST have at most one Attachment Table.

While the Attachment Table lists all the Attachment objects of a Message object, The actual Attachment objects are stored in separate subnodes in the Message object (see the diagram in section [2.4.6.3](#)). Attachment object subnodes are easily identified by having a NID\_TYPE of NID\_TYPE\_ATTACHMENT. Each Attachment object subnode contains a PC with all the properties of the Attachment object, including a property that contains the actual binary data of the Attachment object. The number of Attachment object subnodes MUST match the number of rows in the Attachment Table.

#### 2.4.6.1 Attachment Table

The Attachment Table is a standard TC structure where each of its rows maps to an Attachment object. Each row contains sufficient metadata to identify or display a representation of the Attachment object, but the full Attachment object data is stored in a separate subnode. The

Attachment table is optional, and can be absent from Message objects that do not contain any Attachment objects.

#### 2.4.6.1.1 Attachment Table Template

Each PST MUST have one attachment table template, which is identified with a NID value of NID\_ATTACHMENT\_TABLE (0x671). The attachment table template defines the set of columns for every new Attachment Table that is created. The attachment table template MUST have no data rows, and MUST contain the following property columns.

Property Identifier	Property Type	Friendly Name	Description
0x0E20	PtypInteger32	<b>PidTagAttachmentSize</b>	Size of Attachment object
0x3704	PtypString	<b>PidTagAttachFilenameW</b>	File name of Attachment object
0x3705	PtypInteger32	<b>PidTagAttachMethod</b>	Attachment method
0x370B	PtypInteger32	<b>PidTagRenderingPosition</b>	Rendering position of Attachment object
0x67F2	PtypInteger32	<b>PidTagLtpRowId</b>	LTP Row ID
0x67F3	PtypInteger32	<b>PidTagLtpRowVer</b>	LTP Row Version

#### 2.4.6.1.2 Message object Attachment Tables

Attachment Tables in actual Message objects contain all the columns in the attachment table template, plus a number of extra properties about its Attachment object. Attachment object properties are specified in [\[MS-OXCMMSG\]](#) and [\[MS-OXPROPS\]](#).

#### 2.4.6.1.3 Locating Attachment object Nodes from the Attachment Table

Each row in the Attachment Table maps to an Attachment object subnode in the same way that a Folder object contents table maps its rows to Message object nodes (see section 2.4.4.5.2). The Attachment Table uses theRowIndex in the TC to map rows to Attachment object subnodes. In particular, each **dwRowID** value contains the subnode NID of the Attachment object subnode that corresponds to the row specified by **dwRowIndex**.

### 2.4.6.2 Attachment object PC

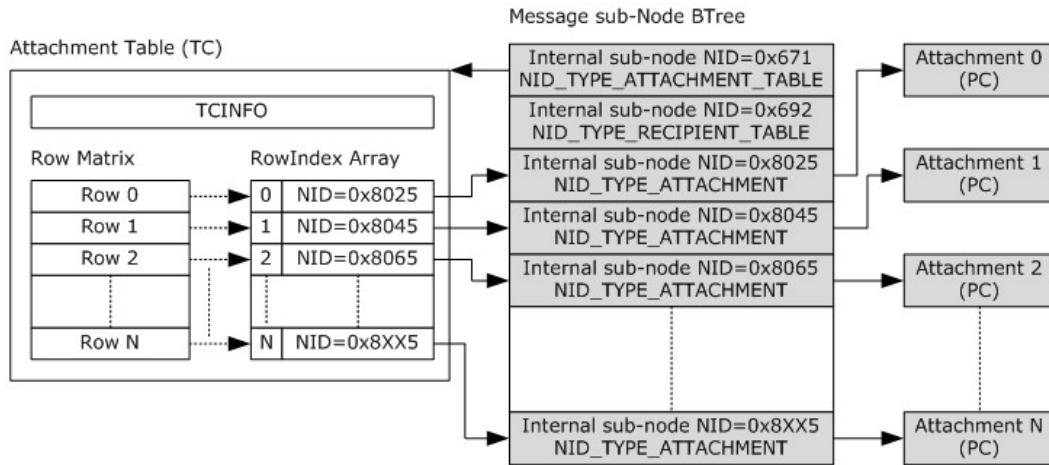

An Attachment object PC is a subnode with a NID\_TYPE of NID\_TYPE\_ATTACHMENT, which contains all the information about an Attachment object. Because of the size of most Attachment objects being quite large, the binary data of the Attachment objects are usually stored in the subnode of the Attachment object node (which is itself a subnode of the Message object node), and often, a data tree is used to store the binary content. The number of Attachment object subnodes in a Message object MUST equal the number of rows in the Attachment Table.

#### 2.4.6.2.1 Property Schema of an Attachment object PC

The basic property schema of a general Message object is specified in [\[MS-OXCMMSG\]](#) and [\[MS-OXPROPS\]](#). From the PST perspective, the following properties MUST be present in any valid Attachment object PC.

Property Identifier	Property Type	Friendly Name	Description
0x0E20	PtypInteger32	PidTagAttachmentSize	Size of Attachment object
0x3705	PtypInteger32	PidTagAttachMethod	Attachment method
0x370B	PtypInteger32	PidTagRenderingPosition	Rendering position of Attachment object

#### 2.4.6.3 Relationship between Attachment Table and Attachment objects

**Figure 12: Relationship between Attachment Table and Attachment objects**

The preceding diagram depicts the mapping between rows in the Attachment Table and the actual Attachment object subnodes using the RowIndex to obtain the subnode NID, and then using the subnode BTree records to locate the BIDs associated with each Attachment object PC.

#### 2.4.7 Named Property Lookup Map

The mapping between NPIDs and property names is done using a special Name-to-ID-Map in the PST, with a special NID of NID\_NAME\_TO\_ID\_MAP (0x61). There is one Name-to-ID-Map per PST. From an implementation point of view, the Name-to-ID-Map is a standard PC with some special properties. Specifically, the properties in the PC do not refer to real property identifiers, but instead point to specific data sections of the Name-to-ID-Map.

A named property is identified by a (GUID, identifier) value pair, otherwise known as the property name. The identifier can be a string or a 16-bit numerical value. The GUID value identifies the **property set** to which the property name is associated. Well-known property names and a list of property set GUIDs are specified in [\[MS-OXPROPS\]](#).

The Name-to-ID-Map (NPMAP) consists of several components: an Entry Stream, a GUID Stream, a String Stream, and a hash table to expedite searching. The following are the data structures used for the NPMAP.

#### 2.4.7.1 NAMEID

Each NAMEID record corresponds to a named property. The contents of the NAMEID record can be interpreted in two ways, depending on the value of the N bit.

Unicode / ANSI:

0	1	2	3	4	5	6	7	8	9	1	0	1	2	3	4	5	6	7	8	9	2	0	1	2	3	4	5	6	7	8	9	3	0	1
dwPropertyID																																		
N	wGuid															wPropIdx																		

**dwPropertyID (4 bytes):** If the **N** field is "1", this value is the byte offset into the String Stream where the string name of the property is stored. If the **N** field is "0", this value contains the value of numerical name.

**N (1 bit):** Named property identifier type. If this value is "1", the named property identifier is a string. If this value is "0", the named property identifier is a 16-bit numerical value.

**wGuid (15 bits):** GUID index. If this value is 1 or 2, the named property's GUID is one of 2 well-known GUIDs. If this value is greater than 2, this value is the index + 3 into the GUID Stream where the GUID associated with this named property is located. The following table explains how the **wGuid** value works.

wGuid	Friendly Name	Description
0x0000	NAMEID_GUID_NONE	No GUID (N=1)
0x0001	NAMEID_GUID_MAPI	The GUID is PS_MAPI ([MS-OXPROPS] section 1.3.2).
0x0002	NAMEID_GUID_PUBLIC_STRINGS	The GUID is PS_PUBLIC_STRINGS ([MS-OXPROPS] section 1.3.2).
0x0003	N/A	GUID is found at the (N-3) * 16 byte offset in the GUID Stream

**wPropIdx (16 bits):** Property index. This is the ordinal number of the named property, which is used to calculate the NPID of this named property. The NPID of this named property is calculated by adding 0x8000 to **wPropIndex**.

#### 2.4.7.2 The GUID Stream

The GUID Stream is a flat array of 16-byte GUID values that contains the GUIDs associated with all the property sets used in all the named properties in the PST. The Entry Stream is stored as a single property in the PC with the property tag **PidTagNameidStreamGuid**.

For each NAMEID record, the **wGuid** field is used to locate the GUID that is associated with the named property. Because each GUID represents a property set that can contain many related properties, it is therefore quite common to have multiple NAMEID records referring to the same GUID.

### 2.4.7.3 The Entry Stream

The Entry Stream is a flat array of NAMEID records that represent all the named properties in the PST. The Entry Stream is stored as a single property in the PC with the property tag **PidTagNameidStreamEntry**.

### 2.4.7.4 The String Stream

The String Stream is a packed list of strings that is used for all the named properties in the PST. The String Stream is stored as a single property in the PC with the property tag **PidTagNameidStreamString**.

The String Stream contains a string Name for every NAMEID record whose N bit is set to "1". The corresponding value in **dwPropertyID** is the byte offset to the beginning of the corresponding Name string in the String Stream. The Name string is in ANSI format for ANSI PSTs, and is in Unicode format for Unicode PSTs. Each string is NULL-terminated as per its respective string format.

### 2.4.7.5 Hash Table

The NPMAP has a hash table to expedite searches without having to scan the various streams. The hash table is mostly used in avoiding duplicates when attempting to add a new named property. The hash table consists of a number of properties in the PC, including a special property that contains the bucket count, and the hash buckets, each bucket being a separate property.

The bucket count is stored in the property **PidTagNameidBucketCount**. This property contains the number of hash buckets in the hash table. The value of this property SHOULD be 251 (0xFB). Implementations, however, MUST always consult **PidTagNameidBucketCount** to obtain the actual bucket count.

Hash buckets start at the property identifier of **PidTagNameidBucketBase**, and are assigned sequentially. The hash bucket property identifiers range from 0x1000 to (0x1000 + (bucket count - 1)).

Given any NAMEID record, the bucket selection is determined using the following formula:

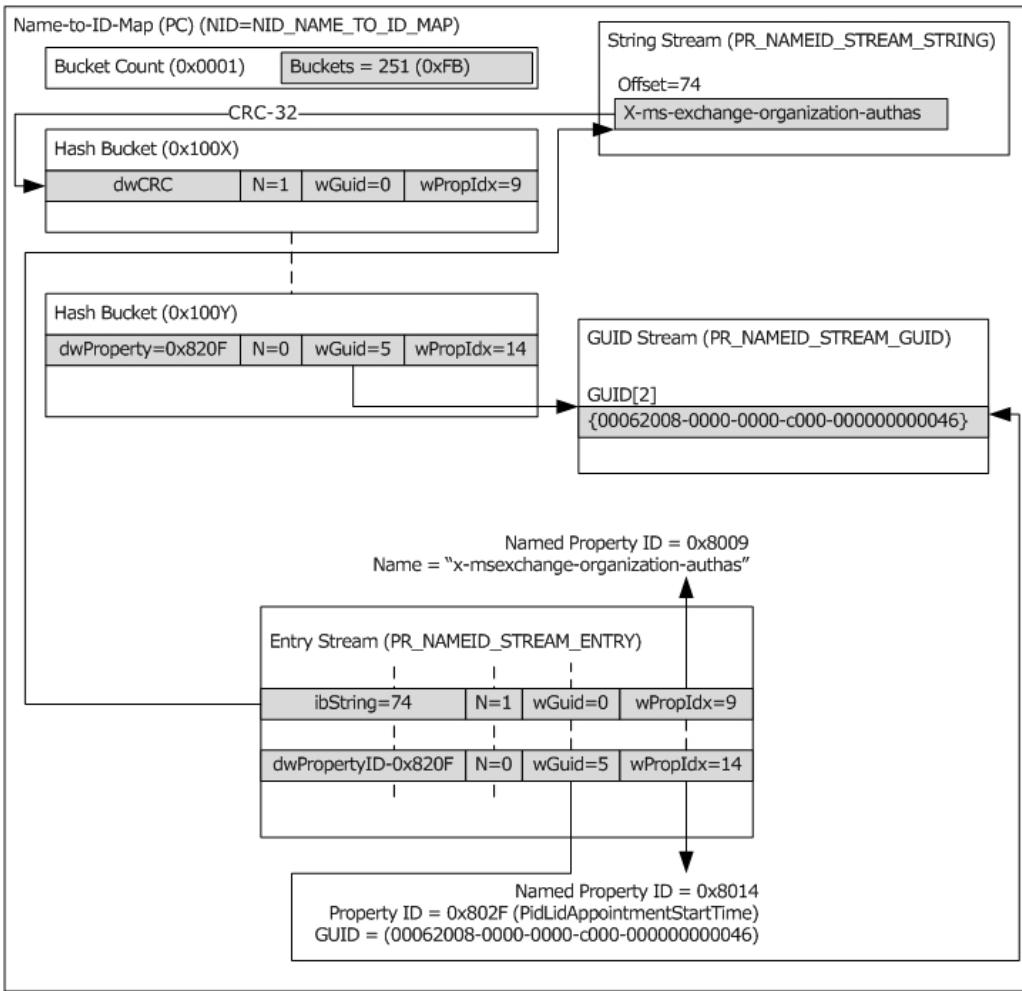

```
NAMEID nameid = { ... }; ULONG *pul = (ULONG *)&nameid; ULONG ulBucket = ((pul[0] ^ (pul[1] & 0xFFFF)) % BucketCount);
```

Each hash bucket contains a flat array of slightly modified NAMEID records. The fields are interpreted as specified in section [2.4.7.1](#), with the following exception. When the **N** field is set to "1", the **dwPropertyID** field contains the CRC32 value of the corresponding string in the String Stream. This is used to quickly identify potential name matches or collisions when searching and inserting named properties, respectively. Note that because of the many-to-one properties of the CRC32 hash, a matching CRC32 value merely indicates the potential of a Name match. An exact match is determined by checking the actual strings.

Each hash bucket can contain up to 8 such modified NAMEID records. The individual records within the bucket are not sorted in any particular order so it is necessary to scan all the records in the bucket to determine if a match is present.

### 2.4.7.6 Data Organization of the Name-to-ID-Map

The following diagram depicts how the various elements of the NPMAP relate to each other, and the two mapping scenarios.

**Figure 13: Data Organization of the Name-to-ID Map**

The preceding diagram shows the Name-to-ID-Map (NPMAP) as a single Property Context, and all the streams and hash table entities as individual properties in the PC.

The top-right case shows the case where the property name is a (GUID, string) value pair. The property identifier 0x8009 is mapped to the name "x-ms-exchange-organization-authas", which is embedded in the String Stream. The **wGuid** field is set to 0, indicating that no GUID is associated with this property name.

The bottom-right case shows the second scenario, where property identifier 0x8014 associated with well-known property name **PidLidAppointmentStartTime**. 0x8014 is also associated with GUID {00062008-0000-0000-C000-000000000046}, which represents the PSETID\_Common property set ([\[MS-OXPROPS\]](#)).

The left column depicts the hash table and how two buckets contain records that refer back to these two named properties. Notice the CRC32 of the string property name is used in the **dwPropertyID** field in the NAMEID record in the hash table.

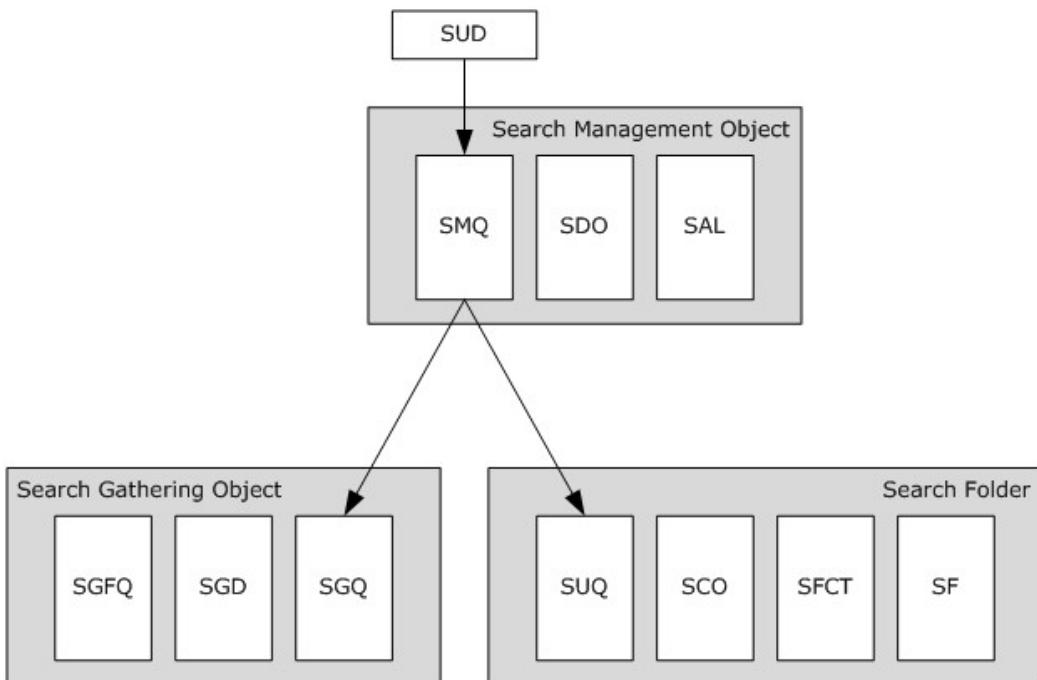

## 2.4.8 Search

A number of objects exist in the PST to support search-related features. This section provides high-level information about the various Search objects that can be found in a PST. The discussion of search-related objects in this document is strictly limited to the scope of providing a brief technical overview of each of the objects, and allowing implementers to perform the necessary update requirements to the search object when changing the contents of the PST.

The following are specific non-goals of this section:

- Provide technical information such that implementations can create search Folder objects and search criteria.
- Provide technical information such that implementations can perform search queue processing and content indexing.

The following diagram depicts the various search objects and their relationship.

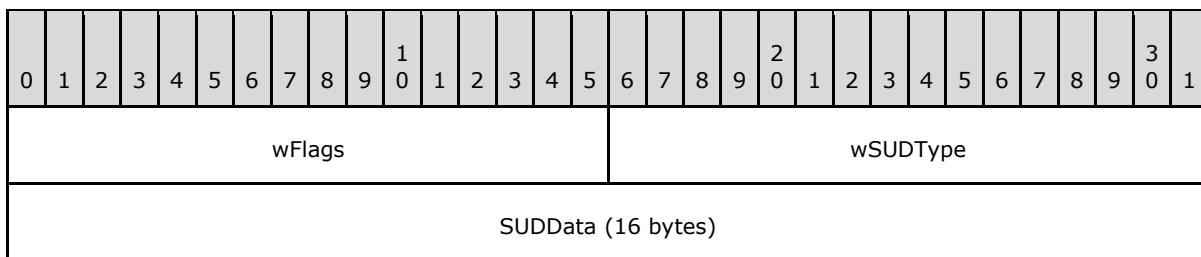

**Figure 14: Search-related Objects**

### 2.4.8.1 Search Update Descriptor (SUD)

The SUD represents a single unit of change that can have an effect on any of the search objects. When a change is made to the contents of a PST (add, modification, removal, and so on), the modifier is responsible to create a SUD that describes the change and queue it into the Search Management Queue (SMQ).

#### 2.4.8.1.1 SUD Structure

Each SUD is represented by SUD structure, which has the following format:

**wFlags (2 bytes):** SUD Flags. Applicable SUD Flags depend on the associated SUD Type. The following table summarizes the SUD Flags defined and their applicability.

Value	Friendly Name	Meaning	Applies To
0x0001	SUDF_PRIORITY_LOW	Change search Folder object priority to foreground	SUDT_SRCH_MOD
0x0002	SUDF_PRIORITY_HIGH	Change search Folder object priority to background	SUDT_SRCH_MOD
0x0004	SUDF_SEARCH_RESTART	Request full rebuild of search Folder object contents	SUDT_SRCH_MOD
0x0008	SUDF_NAME_CHANGED	Display Name of Folder object changed	SUDT_FLD_MOD
0x0010	SUDF_MOVE_OUT_TO_IN	Move from non-SDO domain to SDO domain	SUDT_FLD/MSG_MOV
0x0020	SUDF_MOVE_IN_TO_IN	Move from SDO domain to SDO domain	SUDT_FLD/MSG_MOV
0x0040	SUDF_MOVE_IN_TO_OUT	Move from SDO domain to non-SDO domain	SUDT_MSG_MOV
0x0080	SUDF_MOVE_OUT_TO_OUT	Move between non-SDO domains	SUDT_MSG_MOV
0x0100	SUDF_SPAM_CHECK_SERVER	Make sure <b>spam</b> Message object deleted on server	SUDT_MSG_SPAM
0x0200	SUDF_SET_DEL_NAME	Delegate Root Name of Folder object changed	SUDT_FLD_MOD
0x0400	SUDF_SRCH_DONE	Search is finished for associated object	SUDT_SRCH_MOD
0x8000	SUDF_DOMAIN_CHECKED	Object is validated against the SDO	SUDT_FLD/MSG_*

**wSUDType (2 bytes):** SUD Type. This indicated the type of update that is described in this SUD and is used as the selector field into the appropriate structure to use for **SUDData**. The defined SUD types are as follows.

Value	Friendly Name	Meaning	SUDData Structure
0x00	SUDT_NULL	Invalid SUD Type	None
0x01	SUDT_MSG_ADD	Message added	SUD_MSG_ADD

Value	Friendly Name	Meaning	SUDData Structure
0x02	SUDT_MSG_MOD	Message modified	SUD_MSG_MOD
0x03	SUDT_MSG_DEL	Message deleted	SUD_MSG_DEL
0x04	SUDT_MSG_MOV	Message moved	SUD_MSG_MOV
0x05	SUDT_FLD_ADD	Folder object added	SUD_FLD_ADD
0x06	SUDT_FLD_MOD	Folder object modified	SUD_FLD_MOD
0x07	SUDT_FLD_DEL	Folder object deleted	SUD_FLD_DEL
0x08	SUDT_FLD_MOV	Folder object moved	SUD_FLD_MOV
0x09	SUDT_SRCH_ADD	Search Folder object added	SUD_SRCH_ADD
0x0A	SUDT_SRCH_MOD	Search Folder object modified	SUD_SRCH_MOD
0x0B	SUDT_SRCH_DEL	Search Folder object deleted	SUD_SRCH_DEL
0x0C	SUDT_MSG_ROW_MOD	Message modified, contents table affected	SUD_MSG_MOD
0x0D	SUDT_MSG_SPAM	Message identified as spam	SUD_MSG_SPAM
0x0E	SUDT_IDX_MSG_DEL	Content-indexed Message object deleted	SUD_IDX_MSG_DEL
0x0F	SUDT_MSG_IDX	Message has been indexed	SUD_MSG_IDX

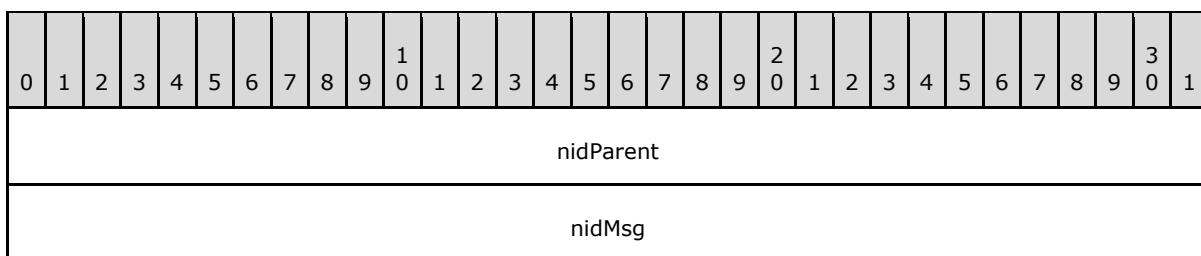

**SUDData (16 bytes):** This is the data associated with the SUD. The structure of this data depends on the SUD Type indicated in **wSUDType**. Details about each structure type are specified in section [2.4.8.2](#).

## 2.4.8.2 SUDData Structures

The following are the definitions of the various **SUDData** structures referenced in the preceding table.

### 2.4.8.2.1 SUD\_MSG\_ADD / SUD\_MSG\_MOD / SUD\_MSG\_DEL Structure

This structure is used to indicate that a Message object has been added, modified or deleted.

**nidParent (4 bytes):** NID of the parent Folder object into which the Message object is added / modified / deleted.

**nidMsg (4 bytes):** NID of the Message object that was added / modified / deleted.

#### 2.4.8.2.2 SUD\_MSG\_MOV Structure

This structure is used to indicate that a Message object has been moved.

0	1	2	3	4	5	6	7	8	9	1	0	1	2	3	4	5	6	7	8	9	2	0	1	2	3	4	5	6	7	8	9	3	0	1
nidParentNew																																		
nidMsg																																		
nidParentOld																																		

**nidParentNew (4 bytes):** NID of the parent Folder object into which the Message object is moved.

**nidMsg (4 bytes):** NID of the Message object that was moved.

**nidParentOld (4 bytes):** NID of the parent Folder object from which the Message object is moved.

#### 2.4.8.2.3 SUD\_FLD\_ADD / SUD\_FLD\_MOV Structure

This structure is used to indicate that a Folder object has been added or moved.

0	1	2	3	4	5	6	7	8	9	1	0	1	2	3	4	5	6	7	8	9	2	0	1	2	3	4	5	6	7	8	9	3	0	1
nidParent																																		
nidFld																																		
dwReserved1																																		
dwReserved2																																		

**nidParent (4 bytes):** NID of the parent Folder object into which the Message object is added / moved.

**nidMsg (4 bytes):** NID of the Folder object that was added / moved.

**dwReserved1 (4 bytes):** Reserved; MUST be set to zero (0).

**dwReserved2 (4 bytes):** Reserved; MUST be set to zero (0).

#### 2.4.8.2.4 SUD\_FLD\_MOD / SUD\_FLD\_DEL Structure

This structure is used to indicate that a Folder object has been modified or deleted.

0	1	2	3	4	5	6	7	8	9	1	0	1	2	3	4	5	6	7	8	9	2	0	1	2	3	4	5	6	7	8	9	3	0	1
nidFld																																		
dwReserved																																		

**nidFld (4 bytes):** NID of the Folder object that was modified / deleted.

**dwReserved (4 bytes):** Reserved. Readers MUST NOT modify this value. Creators of this structure MUST initialize this value to zero (0).

#### 2.4.8.2.5 SUD\_SRCH\_ADD / SUD\_SRCH\_DEL Structure

This structure is used to indicate that a search Folder object has been added or deleted.

0	1	2	3	4	5	6	7	8	9	1	0	1	2	3	4	5	6	7	8	9	2	0	1	2	3	4	5	6	7	8	9	3	0	1
nidSrch																																		

**nidSrch (4 bytes):** NID of the search Folder object that was added / deleted.

#### 2.4.8.2.6 SUD\_SRCH\_MOD Structure

This structure is used to indicate that a search Folder object has been modified.

0	1	2	3	4	5	6	7	8	9	1	0	1	2	3	4	5	6	7	8	9	2	0	1	2	3	4	5	6	7	8	9	3	0	1
nidSrch																																		
dwReserved																																		

**nidSrch (4 bytes):** NID of the search Folder object that was modified.

**dwReserved (4 bytes):** Reserved. Readers MUST NOT modify this value. Creators of this structure MUST initialize this value to zero (0).

#### 2.4.8.2.7 SUD\_MSG\_SPAM Structure

This structure is used to indicate that an incoming Message object had been determined to be spam.

0	1	2	3	4	5	6	7	8	9	1	0	1	2	3	4	5	6	7	8	9	2	0	1	2	3	4	5	6	7	8	9	3	0	1
nidParent																																		

nidMsg
--------

**nidParent (4 bytes):** NID of the parent Folder object that contains the spam Message object.

**nidMsg (4 bytes):** NID of the Message object being identified as spam.

#### 2.4.8.2.8 SUD\_IDX\_MSG\_DEL Structure

This structure is used to indicate that an indexed Message object has been deleted.

0	1	2	3	4	5	6	7	8	9	1	0	1	2	3	4	5	6	7	8	9	2	0	1	2	3	4	5	6	7	8	9	3	0	1
nidParent																																		
nidMsg																																		

**nidParent (4 bytes):** NID of the parent Folder object that contains the deleted Message object.

**nidMsg (4 bytes):** NID of the deleted Message object.

#### 2.4.8.2.9 SUD\_MSG\_IDX Structure

This structure is used to indicate that a Message object was successfully indexed.

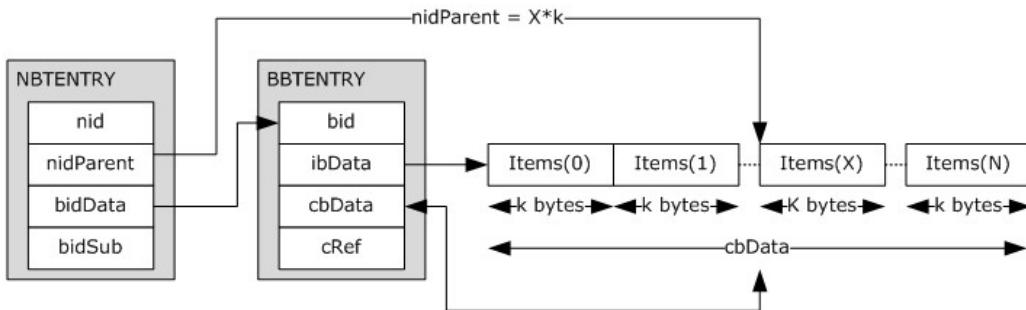

0	1	2	3	4	5	6	7	8	9	1	0	1	2	3	4	5	6	7	8	9	2	0	1	2	3	4	5	6	7	8	9	3	0	1
nidMsg																																		

**nidMsg (4 bytes):** NID of the Message object that was indexed.

#### 2.4.8.3 Basic Queue Node

A number of objects that are referenced in the remainder of this section depend on a shared generic concept of a queue node. In the context of Search, a queue is implemented as a node that contains an array of fixed-size items. To maintain the FIFO properties of a queue, new items are always appended to the end of the array, and items are always removed from the front of the array.

However, the PST implementation of the queue object has a special feature to optimize for speed of access by minimizing the amount of data written. Specifically, when an item is removed from the queue, instead of removing the item from the array and shifting remaining items forward, the **nidParent** field of the queue node is overloaded to be used as a pointer to the "head" of the queue. The following diagram illustrates how this works.

**Figure 15: Basic Queue Structure**

Because a queue is a standalone entity and does not have the concept of a "parent", the **nidParent** field of the queue node is re-purposed to be used as a byte offset pointer to the "head" of the queue. Initially, **nidParent** points to 0 (that is, Item[0]), and new items, each of size  $k$  bytes, are appended to the end of the array as shown. When the first item is removed from the queue, the contents of Items[0] is returned to the caller, and then the value of **nidParent** is updated to point to the next item (that is, Items[1]). Note that **nidParent** stores the byte offset of the "head" of the queue instead of an item index. The number of items in the queue can be determined by dividing **cbData** by  $k$  (that is, the size of each item). Implementations MUST NOT process the contents of a queue if **cbData** is not an integer multiple of  $k$ .

As an implementation detail, when the last item of the queue is removed (that is, `NBTENTRY.nidParent == BBTENTRY.cbData`), the entire queue contents are deleted, and both **nidParent** and **cbData** are reset to zero.

The same generic queue node concept is used throughout this section, except that each type of queue has its own specific value for the size of each item (that is,  $k$ ).

#### 2.4.8.4 Search Management Object (SMO)

The Search Management Object is responsible for tracking all pending search activity in the PST. It consists of three nodes: The Search Management Queue (SMQ), Search Activity List (SAL), and Search Domain Object (SDO).

##### 2.4.8.4.1 Search Management Queue (SMQ)

The Search Management Queue is where all the SUDs are queued when changes are made to the PST contents. There MUST be exactly one instance of the SMQ in each PST, and it is identified by a special NID value of `NID_SEARCH_MANAGEMENT_QUEUE` (0x1e1). Implementation-wise, it uses a basic queue node described in section 2.4.8.3, and each of the items in the SMQ is a SUD Structure described in section 2.4.8.1.1. The SMQ is the master FIFO queue of all pending search activity in the PST.

Any implementation that modifies the contents of the PST in any way MUST queue SUD entries that correspond to the sequence and nature of the modification into the SMQ. Failure to queue the appropriate SUD entries or queuing the SUD entries out-of-order results in search Folder objects going out of sync with the actual contents.

##### 2.4.8.4.2 Search Activity List (SAL)

The Search Activity List is a node that is identified by a special NID value of `NID_SEARCH_ACTIVITY_LIST` (0x201), which contains a simple array of NIDs (not a queue). Each

NID in the SAL corresponds to the NID of a Folder object that has an associated search Folder object. Implementations SHOULD NOT modify the SAL. <[17](#)>

#### **2.4.8.4.3 Search Domain Object (SDO)**

The Search Domain Object is a node that is identified by a special NID value of NID\_SEARCH\_DOMAIN\_OBJECT (0x261), which contains a simple array of NIDs that collectively represent the global search domain of the PST.

#### **2.4.8.5 Search Gatherer Object (SGO)**

The Search Gatherer Object controls all the Content Indexing functionality in the PST. However, because the implementation of Content Indexing is out of the scope of this document, this section only provides a high-level summary of the various objects that are associated with Content Indexing.

##### **2.4.8.5.1 Search Gatherer Queue (SGQ)**

The Search Gatherer Queue is a node that is identified by a special NID value of NID\_SEARCH\_GATHERER\_QUEUE (0x281). It is implemented as a queue node where each of its items is a SUD Structure that contains specific changes that pertain to Content Indexing. Entries in the SGQ are moved from the SMQ to the SGQ during SMQ processing. All SUDs MUST be queued through the SMQ and implementations MUST NOT modify the SGQ in any way.

##### **2.4.8.5.2 Search Gatherer Descriptor (SGD)**

The Search Gatherer Descriptor is a node that is identified by a special NID value of NID\_SEARCH\_GATHERER\_DESCIPRTOR (0x2A1). It contains an opaque, variable-size binary BLOB that provides context for Context Indexing. Implementations MUST NOT modify the SGD in any way.

##### **2.4.8.5.3 Search Gatherer Folder Queue (SGFQ)**

The Search Gatherer Folder Queue is a node that is identified by a special NID value of NID\_SEARCH\_GATHERER\_FOLDER\_QUEUE (0x321), which contains a simple array of NIDs (not a queue). Each NID in the SGFO corresponds to the NID of a Folder object that has related Content Indexing activity. Implementations MUST NOT modify the SGFQ in any way.

#### **2.4.8.6 Search Folder objects**

This section describes the various objects that are associated with search Folder objects. Because it is not the intention of this document to document the creation and maintenance of search Folder object, this section only provides high-level information about these objects so that they can be identified when reading existing PSTs.

##### **2.4.8.6.1 Search Folder object (SF)**

The search Folder object is implemented as a PC that is identified by a special NID\_TYPE of NID\_TYPE\_SEARCH\_FOLDER (0x03). The basic schema requirements of the search Folder object PC are identical to the Folder object PC (section 2.4.4.1).

## 2.4.8.6.2 Search Folder object Contents Table (SFCT)

The search Folder object contents table is a TC node identified with a NID\_TYPE of NID\_TYPE\_SEARCH\_CONTENTS\_TABLE. Its function is to list the Search Message objects in the Folder object, which are Message objects that match the search Folder object's Search Criteria.

### 2.4.8.6.2.1 Search Folder Contents Table Template

Each PST MUST have one search folder contents table template, which is identified with a NID value of NID\_SEARCH\_CONTENTS\_TABLE\_TEMPLATE (0x610). The Search Contents Table Template MUST have no data rows, and MUST contain the following property columns.

Property Identifier	Property Type	Friendly Name	Description
0x0017	PtypInteger32	PidTagImportance	Importance
0x001A	PtypString	PidTagMessageClassW	Message class
0x0036	PtypInteger32	PidTagSensitivity	Sensitivity
0xE07	PtypInteger32	PidTagMessageFlags	Message flags
0xE17	PtypInteger32	PidTagMessageStatus	Message status
0x0037	PtypString	PidTagSubjectW	Subject
0x0042	PtypString	PidTagSentRepresentativeNameW	Sender representative name
0x0057	PtypBoolean	PidTagMessageToMe	Whether recipient is in To: line
0xE03	PtypString	PidTagDisplayCcW	Cc: line
0xE04	PtypString	PidTagDisplayToW	To: line
0xE05	PtypString	PidTagParentDisplayW	Parent Display name
0xE06	PtypTime	PidTagMessageDeliveryTime	Message delivery timestamp
0xE07	PtypInteger32	PidTagMessageFlags	Message flags
0xE08	PtypInteger32	PidTagMessageSize	Message size
0xE17	PtypInteger32	PidTagMessageStatus	Message status
0xE2A	PtypBoolean	PidTagExchangeRemoteHeader	Has Exchange Remote Header
0x3008	PtypTime	PidTagLastModificationTime	Last modification time of Message object
0x67F1	PtypInteger32	PidTagLtpParentNid	LTP Parent NID
0x67F2	PtypInteger32	PidTagLtpRowId	LTP Row ID
0x67F3	PtypInteger32	PidTagLtpRowVer	LTP Row Version

### 2.4.8.6.3 Search Update Queue (SUQ)

The Search Update Queue is a node that is identified by a special NID\_TYPE of NID\_TYPE\_SEARCH\_UPDATE\_QUEUE (0x06). It is implemented as a queue node where each of its items is a SUD Structure that contain specific changes that pertain to Search activity of this particular search Folder object. Entries in the SUQ are moved from the SMQ to the Folder object's SUQ during SMQ processing. All SUDs MUST be queued through the SMQ and implementations MUST NOT modify the SUQ in any way.

### 2.4.8.6.4 Search Criteria Object (SCO)

The Search Criteria Object is a PC that is identified by a special NID\_TYPE of NID\_TYPE\_SEARCH\_CRITERIA\_OBJECT (0x07). The properties in the PC collectively represent the specific Search Criteria for the search Folder object. The specific properties used by the SCO are out of the scope of this document. Implementations MUST NOT modify the SCO in any way.

## 2.5 Calculated Properties

Calculated properties are properties that are not physically stored in the PST as individual properties. Instead, these properties are derived or calculated in one way or another. This section defines the list of calculated properties and the mechanisms through which the values of these properties are evaluated, discovered, modified and otherwise manipulated.

The following is a comprehensive list of calculated properties defined for the PST. The properties are grouped by Object Type. Note that for an ANSI PST, all string properties are stored in ANSI encoding, whereas a Unicode PST stores all string properties in Unicode encoding. Implementations MUST support retrieving string properties in either **PtypString8** or **PtypString** formats.

### 2.5.1 Attributes of a Calculated Property

A calculated property has six attributes, which are represented by the six columns in each of the calculated property tables. These Attributes collectively determine how the property value is calculated and the behavior characteristics on Get / Set / Delete and List operations. The following table lists these Attributes and their description.

Attribute	Description
Property Tag	The property tag used to access the property at the Messaging Layer.
Base Tag	The internal property tag of the corresponding property, if applicable. If specified, this is the property tag that is used to store the related property value in the PC or TC. In most cases, the value stored in the base property is further manipulated to calculate the actual property value.
Get Behavior	This describes how the property value is calculated. In most cases, the get operations refers to an SPGET_* operation, which describes how to calculate the property value. All the SPGET codes are defined later in this section. In some cases, the property value is retrieved directly from the PC.
Set Behavior	Whether the property can be modified, and if so, whether there are special remarks or side effects. Set behavior is discussed in further detail after the Get Behavior.
Delete Behavior	Whether the property can be deleted. There are a few special cases that have some side effects.
List	This column describes the visibility of the calculated property in the event of an "Enumerate

Attribute	Description
Behavior	All Properties" query.

Implementations MUST follow the documented Get / Set / Delete and List behaviors while accessing these properties.

In the event where the ANSI and Unicode versions support different sets of special properties, they are defined separately. Rows that are different between the ANSI and Unicode versions are shaded in gray.

## 2.5.2 Calculated Properties by Object Type

The following are the list of Messaging Objects and the corresponding list of calculated properties for that object type.

### 2.5.2.1 Message store

The following are the calculated properties defined under the Message store. Note that "nid" and "nidParent" in the "Base Tag" column refers to the **nid** and the **nidParent** fields of the current object node.

ANSI / Unicode:

Property Tag	Base Tag	Get Behavior	Set	Delete	List
<b>PidTagReplFlags</b>		PC	PC	PC	ALLOW
<b>PidTagAssociatedSharingProvider</b>		PC	PC	PC	ALLOW
<b>PidTagMappingSignature</b>		SPGET_MAPSIG	N	N	ALWAYS
<b>PidTagRecordKey</b>		SPGET_UIDRESOURCE	N	N	ALLOW
<b>PidTagStoreRecordKey</b>		SPGET_UIDRESOURCE	N	N	ALWAYS
<b>PidTagStoreEntryId</b>		SPGET_STOREID	N	N	ALWAYS
<b>PidTagObjectType</b>	nid	SPGET_OBJECTTYPE	N	N	ALWAYS
<b>PidTagEntryId</b>		SPGET_STOREID	N	N	ALWAYS
<b>PidTagDisplayName</b>		PC	PC	N	ALLOW
<b>PidTagStoreState</b>		SPGET_STORESTATE	N	N	ALWAYS
<b>PidTagStoreProvider</b>		SPGET_UIDPROVIDER	N	N	ALWAYS
<b>PidTagReceiveFolderSettings</b>		SPGET_TRUE	N	N	ALWAYS

### 2.5.2.2 Folder objects

The following are the calculated properties defined under the Folder object.

ANSI / Unicode:

<b>Property Tag</b>	<b>Base Tag</b>	<b>Get Behavior</b>	<b>Set</b>	<b>Delete</b>	<b>List</b>
<b>PidTagParentEntryId</b>	nidParent	SPGET_PARENTID	N	N	ALWAYS
<b>PidTagReplItemid</b>		SPGET_TABLE_ONLY	N	N	NEVER
<b>PidTagReplFolderid</b>	nidParent	SPGET_FOLDERID	SPSET_FID	N	NEVER
<b>PidTagReplChangenum</b>	nid	SPGET_TABLE_ONLY	N	N	NEVER
<b>PidTagReplVersionhistory</b>		SPGET_TABLE_ONLY	N	N	NEVER
<b>PidTagReplFlags</b>		SPGET_TABLE_ONLY	N	N	NEVER
<b>PidTagReplCopiedfromVersionhistory</b>		SPGET_TABLE_ONLY	N	N	NEVER
<b>PidTagReplCopiedfromitemid</b>		SPGET_TABLE_ONLY	N	N	NEVER
<b>PidTagProvideritemid</b>	nid	SPGET_PROV_ITEMID	N	N	NEVER
<b>PidTagMappingSignature</b>		SPGET_MAPSIG	N	N	ALWAYS
<b>PidTagRecordKey</b>	nid	SPGET_RECORDKEY	N	N	ALWAYS
<b>PidTagStoreRecordKey</b>		SPGET_UIDRESOURCE	N	N	ALWAYS
<b>PidTagStoreEntryId</b>		SPGET_STOREID	N	N	ALWAYS
<b>PidTagObjectType</b>	nid	SPGET_OBJECTTYPE	N	N	ALWAYS
<b>PidTagEntryId</b>	nid	SPGET_EID	N	N	ALWAYS
<b>PidTagAttributeHidden</b>		PC	PC	PC	ALLOW
<b>PidTagDisplayName</b>		PC	PC	N	ALLOW
<b>PidTagStoreProvider</b>		SPGET_UIDPROVIDER	N	N	ALWAYS
<b>PidTagFolderType</b>	nid	SPGET_FOLDERTYPE	N	N	ALWAYS
<b>PidTagContentCount</b>	PR_CONTENT_C	SPGET_CONTENT_C	N	N	ALLOW

<b>Property Tag</b>	<b>Base Tag</b>	<b>Get Behavior</b>	<b>Set</b>	<b>Delete</b>	<b>List</b>
	OUNT	OUNT			W
<b>PidTagContentUnreadCount</b>	PR_CONTENT_UNREAD	SPGET_UNREAD_CO UNT	N	N	ALLO W
<b>PidTagSubfolders</b>		PC	N	N	ALLO W
<b>PidTagContainerHierarchy</b>		SPGET_TRUE	N	N	ALWA YS
<b>PidTagContainerContents</b>		SPGET_TRUE	N	N	ALWA YS
<b>PidTagFolderAssociatedContent s</b>		SPGET_TRUE	N	N	ALWA YS
<b>PidTagExtendedFolderFlags</b>		PC	PC	PC	ALLO W
<b>PidTagShortTermParentEntryId FromObject</b>	nidParent	SPGET_PARENTEID	N	N	NEVE R
<b>PidTagShortTermEntryIdFromO bject</b>	nid	SPGET_EID	N	N	NEVE R
<b>PidTagPstIpmsuBTreeDescenda nt</b>	nid	SPGET_IPMSUBTRE E_DESC	N	N	NEVE R

### 2.5.2.3 Message objects

The following are the calculated properties defined under the Message object.

ANSI / Unicode:

<b>Property Tag</b>	<b>Base Tag</b>	<b>Get Behavior</b>	<b>Set</b>	<b>Delete</b>	<b>List</b>
<b>PidTagMessageClass</b>		PC	SPSET_ MC	N	ALLO W
<b>PidTagSubject</b>	PidTagSubject	SPGET_SUBJECT	SPSET_ SP	DEL_1	ALLO W
<b>PidTagSubjectPrefix</b>	PidTagSubject	SPGET SUBJECTPREFI X	SPSET_ SUB	DEL_1	BASE D
<b>PidTagConversationTopic</b>		PC	SPSET_ CID	DEL_5	ALLO W
<b>PidTagConversationIndex</b>		PC	SPSET_ CID	DEL_5	ALLO W
<b>PidTagDisplayBcc</b>	PidTagDisplay Bcc	SPGET_DISPLAY	N	N	ALWA YS
<b>PidTagDisplayCc</b>	PidTagDisplay	SPGET_DISPLAY	PC	N	ALWA YS

<b>Property Tag</b>	<b>Base Tag</b>	<b>Get Behavior</b>	<b>Set</b>	<b>Delete</b>	<b>List</b>
	Cc				YS
<b>PidTagDisplayTo</b>	PidTagDisplayTo	SPGET_DISPLAY	PC	N	ALWAYS
<b>PidTagMessageFlags</b>		PC	SPSET_MF	N	ALLOW
<b>PidTagMessageSize</b>		PC	PC	N	ALLOW
<b>PidTagParentEntryId</b>	nidParent	SPGET_PARENTEID	N	N	ALWAYS
<b>PidTagMessageRecipients</b>		SPGET_TRUE	N	N	ALWAYS
<b>PidTagMessageAttachments</b>		SPGET_TRUE	N	N	ALWAYS
<b>PidTagMessageStatus</b>		SPGET_MSGSTATUS	N	N	ALLOW
<b>PidTagHasAttachments</b>	PidTagMessageFlags	SPGET_HASATTACH	N	N	ALWAYS
<b>PidTagNormalizedSubject</b>	PidTagSubject	SPGET_NORMALIZEDSUBJECT	N	N	BASED
<b>PidTagRtfInSync</b>		SPGET_RTF_IN_SYNC	SPSET_RIS	SP_DFL4	ALWAYS
<b>PidTagReplitemid</b>		SPGET_TABLE_ONLY	N	N	NEVER
<b>PidTagReplFolderid</b>	nidParent	SPGET_FOLDERID	SPSET_FID	N	NEVER
<b>PidTagReplChangenum</b>	nid	SPGET_TABLE_ONLY	N	N	NEVER
<b>PidTagReplVersionhistory</b>		SPGET_TABLE_ONLY	N	N	NEVER
<b>PidTagReplFlags</b>		SPGET_TABLE_ONLY	N	N	NEVER
<b>PidTagReplCopiedfromVersionhistory</b>		SPGET_TABLE_ONLY	N	N	NEVER
<b>PidTagReplCopiedfromitemid</b>		SPGET_TABLE_ONLY	N	N	NEVER
<b>PidTagProvideritemid</b>	nid	SPGET_PROV_ITEMID	N	N	NEVER
<b>PidTagProviderParentitemid</b>	nidParent	SPGET_PROV_ITEMID	N	N	NEVER

<b>Property Tag</b>	<b>Base Tag</b>	<b>Get Behavior</b>	<b>Set</b>	<b>Delete</b>	<b>List</b>
<b>PidTagMappingSignature</b>		SPGET_MAPSIG	N	N	ALWAYS
<b>PidTagRecordKey</b>		SPGET_RECORDKEY	N	N	ALWAYS
<b>PidTagStoreRecordKey</b>		SPGET_UIDRESOURCE	N	N	ALWAYS
<b>PidTagStoreEntryId</b>		SPGET_STOREID	N	N	ALWAYS
<b>PidTagObjectType</b>	nid	SPGET_OBJECTTYPE	N	N	ALWAYS
<b>PidTagEntryId</b>	nid	SPGET_EID	N	N	ALWAYS
<b>PidTagBody</b>		SPGET_BB_BODY	SPSET_BBB	DEL_2	BODY

#### 2.5.2.4 Embedded Message objects

The following are the calculated properties defined under the embedded Message object.

ANSI / Unicode:

<b>Property Tag</b>	<b>Base Tag</b>	<b>Get Behavior</b>	<b>Set</b>	<b>Delete</b>	<b>List</b>
<b>PidTagMessageClass</b>		PC	SPGET_MC	N	ALLOW
<b>PidTagSubject</b>	PidTagSubject	SPGET SUBJECT	SPGET_SUB	DEL_1	ALLOW
<b>PidTagSubjectPrefix</b>	PidTagSubject	SPGET SUBJECTPREFIX	SPGET_SP	DEL_1	BASED
<b>PidTagConversationTopic</b>		PC	SPSET_CID	DEL_5	ALLOW
<b>PidTagConversationIndex</b>		PC	SPSET_CID	DEL_5	ALLOW
<b>PidTagDisplayBcc</b>	PidTagDisplayBcc	SPGET_DISPLAY	N	N	ALWAYS
<b>PidTagDisplayCc</b>	PidTagDisplayCc	SPGET_DISPLAY	PC	N	ALWAYS
<b>PidTagDisplayTo</b>	PidTagDisplayTo	SPGET_DISPLAY	PC	N	ALWAYS
<b>PidTagMessageFlags</b>		PC	SPSET_	N	ALLOW

<b>Property Tag</b>	<b>Base Tag</b>	<b>Get Behavior</b>	<b>Set</b>	<b>Delete</b>	<b>List</b>
			MF		W
<b>PidTagMessageSize</b>		PC	PC	N	ALLOW
<b>PidTagParentEntryId</b>	nidParent	SPGET_PARENTID	N	N	ALWAYS
<b>PidTagMessageRecipients</b>		SPGET_TRUE	N	N	ALWAYS
<b>PidTagMessageAttachments</b>		SPGET_TRUE	N	N	ALWAYS
<b>PidTagHasAttachments</b>	PidTagMessageFlags	SPGET_HASATTACH	N	N	ALWAYS
<b>PidTagNormalizedSubject</b>	PidTagSubject	SPGET_NORMALIZEDSUBJECT	N	N	BASED
<b>PidTagMappingSignature</b>		SPGET_MAPSIG	N	N	ALWAYS
<b>PidTagRecordKey</b>		SPGET_RECORDKEY	N	N	ALWAYS
<b>PidTagStoreRecordKey</b>		SPGET_UIDRESOURCE	N	N	ALWAYS
<b>PidTagStoreEntryId</b>		SPGET_STOREID	N	N	ALWAYS

<b>PidTagEntryId</b>	nid	SPGET_EID	N	N	ALWAYS
<b>PidTagBody</b>		SPGET_BB_BODY	SPSET_BBB	DEL_2	BODY
<b>PidTagRtfSyncBodyCrc</b>		SPGET_RTF_AUX	SPSET_RA	DEL_3	NEVER
<b>PidTagRtfSyncBodyCount</b>		SPGET_RTF_AUX	SPSET_RA	DEL_3	NEVER
<b>PidTagRtfSyncBodyTag</b>		SPGET_RTF_AUX	SPSET_RA	DEL_3	NEVER
<b>PidTagRtfCompressed</b>		SPGET_BB_BODY	SPSET_BBB	DEL_2	BODY
<b>PidTagRtfSyncPrefixCount</b>		SPGET_RTF_AUX	SPSET_RA	DEL_3	NEVER
<b>PidTagRtfSyncTrailingCount</b>		SPGET_RTF_AUX	SPSET_RA	DEL_3	NEVER

<b>Property Tag</b>	<b>Base Tag</b>	<b>Get Behavior</b>	<b>Set</b>	<b>Delete</b>	<b>List</b>
<b>PidTagBodyHtml (ANSI ONLY)</b>	PidTagHtml	SPGET_BODYHTMLA	SPSET_BBB	DEL_2	BODY
<b>PidTagHtml</b>		SPGET_BB_BODY	SPSET_BBB	DEL_2	BODY
<b>PidTagCreationTime</b>		PC	PC	N	ALLOW
<b>PidTagLastModificationTime</b>		PC	PC	N	ALLOW
<b>PidTagSearchKey</b>		PC	PC	N	ALLOW
<b>PidTagConversationId</b>		SPGET_CONVERSATION_ID	N	DEL_5	ALLOW
<b>PidTagConversationIndexTracking</b>		PC	SPSET_CID	DEL_5	ALLOW
<b>PidTagStoreProvider</b>		SPGET_UIDPROVIDER	N	N	ALWAYS
<b>PidTagContentFilterSpamConfidenceLevel</b>		SPGET_CONTENT_FILE_R_SCL	N	PC	NEVER
<b>PidTagSecureSubmitFlags</b>		SPGET_SECURE_SUBMIT_FLAGS	N	PC	NEVER
<b>PidTagPstBestBodyProptag</b>		SPGET_BB_PROPTAG	N	N	NEVER

### 2.5.2.5 Attachment objects

The following are the calculated properties defined under the Attachment object.

ANSI / Unicode:

<b>Property Tag</b>	<b>Base Tag</b>	<b>Get Behavior</b>	<b>Set</b>	<b>Delete</b>	<b>List</b>
<b>PidTagAttachSize</b>		PC	N	N	ALLOW
<b>PidTagAttachNumber</b>	nid	SPGET_LONGNID	N	N	ALWAYS
<b>PidTagMappingSignature</b>		SPGET_MAPSIG	N	N	ALWAYS
<b>PidTagRecordKey</b>	nid	SPGET_RECORDKEY	N	N	ALWAYS
<b>PidTagStoreRecordKey</b>		SPGET_UIDRESOURCE	N	N	ALWAYS
<b>PidTagStoreEntryId</b>		SPGET_STOREID	N	N	ALWAYS
<b>PidTagObjectType</b>	nid	SPGET_OBJECTTYPE	N	N	ALWAYS

<b>Property Tag</b>	<b>Base Tag</b>	<b>Get Behavior</b>	<b>Set</b>	<b>Delete</b>	<b>List</b>
<b>PidTagAttachMethod</b>		PC	PC	N	ALLOW
<b>PidTagRenderingPosition</b>		PC	PC	N	ALLOW
<b>PidTagSecureSubmitFlags</b>		SPGET_SECURE_SUBMIT_FLAGS	N	PC	NEVER

### 2.5.3 Calculated Property Behaviors

The following are the definitions of the Get / Set / Delete / List behavior descriptors used in the preceding tables.

#### 2.5.3.1 Behavior Descriptors for Get Operations

The following is a list of Behavior Descriptors that relate to Get operations used in the preceding tables, which explain how each specific calculated property is evaluated. In the evaluation column, the use of angle braces (< >) around a property tag is used to denote the value of that property.

<b>Mnemonic</b>	<b>Evaluation</b>	<b>Input Data for Evaluation</b>
PC	The property value is loaded directly from the PC (that is, no special "calculations" are required). However the property has special instructions for Set, Delete and/or List operations.	See the "Base Tag" column for the underlying PC property
SPGET_EID	Returns the PST-specific EntryID of the object in question. See section <a href="#">2.4.3.2</a> for details regarding the conversion between an EntryID and its corresponding NID.	Node.nid
SPGET_STOREEID	Returns the EntryID for the current PST Message store. The EntryID of the Message store is stored in the <b>PidTagEntryId</b> property of the Message store PC.	<b>PidTagEntryId</b> (Message store PC only)
SPGET_LONGNID	Returns Node.nid	Node.nid
SPGET_RECORDKEY	Returns Node.nid	Node.nid
SPGET_UIDRESOURCE	Returns identical value as SPGET_STOREEID	<b>PidTagEntryId</b> (Message store PC only)
SPGET_TRUE	Returns TRUE	None
SPGET_OBJECTTYPE	Returns the object type of the current object. Implementations MUST return one of the pre-defined values: MAPI_STORE MAPI_FOLDER MAPI_MESSAGE	None

Mnemonic	Evaluation	Input Data for Evaluation
	MAPI_ATTACH	
SPGET_FOLDERTYPE	Returns the type of the current Folder object. Implementations MUST return one of the possible values: FOLDER_ROOT FOLDER_GENERIC FOLDER_SEARCH	None
SPGET_UIDPROVIDER	Returns the Provider UID for the current PST. This value is stored in the <b>PidTagRecordKey</b> property of the Message store PC.	<b>PidTagEntryId</b> (Message store PC only)
SPGET_NORMALIZESUBJECT	Returns the Unicode/ANSI version of <b>PidTagNormalizedSubject</b> according to the PST version based on the requested string type. See section <a href="#">2.5.3.1.1</a> for extracting the normalized subject of a Message object.	<b>PidTagNormalizedSubject</b>
SPGET_PARENTENTRYID	Returns the EntryID representation (see section <a href="#">2.4.3.2</a> ) of the NID of the parent of the current object.	Node. <b>nidParent</b>
SPGET_HASATTACH	Returns 1 if <b>PidTagMessageFlags</b> contains MSGFLAG_HASATTACH, 0 otherwise.	<b>PidTagMessageFlags</b>
SPGET_STORESTATE	Returns STORE_HAS_SEARCHES if a node with NID_NID_SEARCH_ACTIVITY_LIST is found. 0 otherwise	None
SPGET_SUBJECTPREFIX	Returns the Unicode/ANSI version of <b>PidTagSubjectPrefix</b> based on the requested string type. See section <a href="#">2.5.3.1.1</a> for extracting the subject prefix of a Message object.	<b>PidTagSubjectPrefix</b>
SPGET SUBJECT	Returns the Unicode/ANSI version of <b>PidTagSubject</b> based on the requested string type. See section <a href="#">2.5.3.1.1</a> for extracting the subject of a Message object.	<b>PidTagSubject</b>
SPGET_DISPLAY	If the "Base Tag" property exists, then its value is returned, otherwise, an empty string in the correct encoding (Unicode/ANSI) is returned based on the requested string type.	See "Base Tag" column
SPGET_ZERO	Returns 0	None
SPGET_MAPSIG	Returns the Mapping Signature UID. This is identical to	See SPGET_UIDPROVIDER

Mnemonic	Evaluation	Input Data for Evaluation
	SPGET_UIDPROVIDER.	
SPGET_BB_BODY	Returns the most appropriate Message object body format based on the requested property tag.	Any of <b>PidTagBody</b> , <b>PidTagHtml</b> , or <b>PidTagRtfCompressed</b>
SPGET_RTF_IN_SYNC	Returns TRUE if the RTF version of the Message object body exists and is in sync with the order versions of the Message object body (if any), or FALSE otherwise.	<b>PidTagRtfCompressed</b> and <b>PidTagRtfInSync</b>
SPGET_MSGSTATUS	Returns <b>PidTagMessageStatus</b> retrieved from the Contents TC from the parent Folder object of the Message object. Implementations MUST follow this method when retrieving this property.	<b>PidTagMessageStatus</b> (from Contents TC of parent Folder object)
SPGET_RTF_AUX	Returns the synchronized values of the requested RTF auxiliary property. If the RTF content is not in sync, the RTF MUST first be synchronized before the property value is retrieved and returned.	Any of <b>PidTagRtfSyncBodyCrc</b> , <b>PidTagRtfSyncBodyCount</b> , <b>PidTagRtfSyncBodyTag</b> , <b>PidTagRtfSyncPrefixCount</b> , or <b>PidTagRtfSyncTrailingCount</b>
SPGET_BODYHTMLA	Returns the HTML rendering of the Message object body. If <b>PidTagHtml</b> is found in the PC, its value MUST be returned. Otherwise, the HTML rendering of the Message object body SHOULD be generated from the other Message object body formats and returned. This property only exists in ANSI versions of the PST and the HTML rendering MUST be returned in ANSI encoding.	<b>PidTagHtml</b>
SPGET_FOLDERID	Returns <b>PidTagReplItemid</b> of the containing Folder object for a Message object or Folder object.	<b>PidTagReplItemid</b> (from parent Folder object PC)
SPGET_TABLE_ONLY	Retrieves and returns the requested property from the appropriate parent Folder object TC (Hierarchy, Contents, or Assoc Contents, based on the requesting object type).	Any of <b>PidTagReplItemid</b> , <b>PidTagReplChangenum</b> , <b>PidTagReplVersionhistory</b> , <b>PidTagReplFlags</b> , <b>PidTagReplCopiedfromVersionhistory</b> , or <b>PidTagCopiedfromitemid</b> (from appropriate parent Folder object TC)
SPGET_HST_FOLDERREPL	Returns TRUE if <b>PidTagContainerClass</b> exists and is set to "IPF.Note", "IPF.Contact", "IPF.Appointment" or an empty string. Returns FALSE otherwise.	<b>PidTagContainerClass</b>

Mnemonic	Evaluation	Input Data for Evaluation
SPGET_IPMSUBTREE_DESC	Returns TRUE if the current object is a descendant object of the IPM SuBTree, FALSE otherwise.	Node.nid
SPGET_BB_PROPTAG	Returns the property tag of the best Message object body format. The typical order of preference for best Message object body is as follows: <b>PidTagRtfCompressed</b> (only if <b>PidTagRtfInSync</b> =TRUE) <b>PidTagHtml</b> <b>PidTagBody</b> Note that the best Message object body format can be explicitly set to override the default preference.	<b>PidTagRtfCompressed,</b> <b>PidTagRtfInSync,</b> <b>PidTagHtml,</b> <b>PidTagBody</b>
SPGET_SUBTREE_CONTAINER	Returns the subTree container of the current object. For a PST, the valid return values are SUBTRECONTAINER_NONE or SUBTRECONTAINER_IPM_SUBTREE.	Node.nid
SPGET_PROVIDERTITEMID	Returns the endian-swapped value of the requested property.	<b>PidTagProviderItemid</b> or <b>PidTagProviderParentItemid</b>
SPGET_UNREAD_COUNT	If <b>PidTagPstHiddenUnread</b> exists, return <b>(PidTagContentUnread - PidTagPstHiddenUnread)</b> , otherwise return <b>PidTagContentUnread</b> .	<b>PidTagContentUnread</b> , and <b>PidTagPstHiddenUnread</b>
SPGET_CONTENT_COUNT	If <b>PidTagPstHiddenCount</b> exists, return <b>(PidTagContentCount - PidTagPstHiddenCount)</b> , otherwise return <b>PidTagContentCount</b> .	<b>PidTagContentCount</b> , and <b>PidTagPstHiddenCount</b>
SPGET_SECURE_SUBMIT_FLAGS	Returns 0	None
SPGET_CONTENT_FILTER_SCI	Returns 0	None
SPGET_CONVERSATION_ID	Returns the computed conversation ID from <b>PidTagConversationIndex</b> , <b>PidTagConversationTopic</b> and <b>PidTagConversationIndexTracking</b> . Refer to section <a href="#">5.4</a> for the algorithm used to compute the Conversation ID value using these properties.	<b>PidTagConversationIndex</b> , <b>PidTagConversationTopic</b> and <b>PidTagConversationIndexTracking</b>

### 2.5.3.1.1 Message Subject Handling Considerations

A message subject consists of two distinct parts: a Subject Prefix (which can be an empty string), and the Normalized Subject. The Message Subject is physically stored in a Message object PC as the **PidTagSubject** property, which includes the entire message subject line, plus some metadata that allows the reader to parse out the Subject Prefix and Normalized Subject.

The following explains the data layout of the binary data stored in **PidTagSubject**, and how to extract the Subject Prefix (**PidTagSubjectPrefix**) and Normalized Subject (**PidTagNormalizedSubject**) fields from **PidTagSubject**.

#### 2.5.3.1.1.1 Obtaining the prefix and normalized subject from PidTagSubject

The first character of **PidTagSubject** indicates whether metadata exists to tell the reader how to parse the prefix and normalized subject. Note that a character is a 1-byte CHAR for an ANSI PST file, and a 2-byte WCHAR for a Unicode PST file.

If the first character contains the value of 1 (the actual value 1, not the ASCII code for the character "1"), then the next character indicates the length of the Subject Prefix, including the separator between the prefix and the normalized subject (a space character in most cases). The Normalized Subject immediately follows the Subject Prefix.

However, if the first character is not 1, then the string contains the entire message subject, with no additional metadata. In this case, the message subject MUST be parsed to extract the prefix and normalized subject.

#### 2.5.3.1.1.2 Rules for parsing the Subject Prefix

The subject prefix is defined as a series of one to three non-space, non-numerical characters that is followed by a colon (""). Zero or more space characters (that is, " " - other whitespace characters are not allowed) can exist after the colon and before the start of the normalized subject.

### 2.5.3.2 Behavior Descriptors for Set Operations

Modifying the value of a calculated property is more complicated than retrieving its value in that a reverse calculation needs to be performed to calculate the new underlying value, and in some cases, more than one underlying property has to be updated as a result.

The following is a list of Behavior Descriptors that relate to Set operations, which describes the actions required to update the pertinent information, as well as any PC properties that are affected as a result of the Set operation.

Mnemonic	Action	Affected PC Properties
N	Property MUST NOT be modified	None
PC	The property value is written directly to the PC (that is, no special "calculations" are required). However the property has special instructions for Get, Delete and/or List operations.	Only the modified property itself
SPSET_MF	Refreshes <b>PidTagMessageFlags</b> based on the current state of the Message object. This involves checking many properties, including the various versions of the Message object body, the recipient and attachment tables,	<b>PidTagMessageFlags</b>

Mnemonic	Action	Affected PC Properties
	and so on.	
SPSET_SP	Sets the subject prefix for the Message object, which MAY affect other Subject-related properties.	<b>PidTagSubjectPrefix</b> , <b>PidTagSubject</b> , and/or <b>PidTagNormalizedSubject</b>
SPSET_SUB	Sets the subject of the Message object. This MAY have cascading effects to the other Subject-related fields.	<b>PidTagSubjectPrefix</b> , <b>PidTagSubject</b> , and/or <b>PidTagNormalizedSubject</b>
SPSET_MC	Sets the message class for the Message object. Implementations MUST check the new message class and reject invalid message classes.	<b>PidTagMessageClass</b>
SPSET_RA	Sets the specified Auxiliary RTF. Modifying one Auxiliary property MAY have cascading effects to other properties. Implementations MUST ensure all the Auxiliary RTF properties stay synchronized.	<b>PidTagRtfSyncBodyCrc</b> , <b>PidTagRtfSyncBodyCount</b> , <b>PidTagRtfSyncBodyTag</b> , <b>PidTagRtfSyncPrefixCount</b> , and/or <b>PidTagRtfSyncTrailingCount</b>
SPSET_RIS	Writes through to the <b>PidTagRtfInSync</b> , with potential side effects to any of the Best Body properties.	<b>PidTagRtfCompressed</b> , <b>PidTagHtml</b> , <b>PidTagBody</b> , or <b>PidTagBodyHtml</b> (ANSI PST only)
SPSET_BBB	Sets the Message object body for the specified body property. This also establishes the specified Message object body type as the best Message object body.	<b>PidTagRtfCompressed</b> , <b>PidTagHtml</b> , <b>PidTagBody</b> , or <b>PidTagBodyHtml</b> (ANSI PST only)
SPSET_CID	Sets the specified property and causes the <b>PidTagConversationId</b> to be recalculated. Refer to section <a href="#">5.4</a> for the algorithm used to compute the Conversation ID value using these properties.	<b>PidTagConversationId</b>

### 2.5.3.3 Behavior Descriptors for Delete Operations

The following is a list of Behavior Descriptors that relate to Delete operations (that is, deleting the property value altogether).

Mnemonic	Action	Side Effects
N	Property MUST NOT be deleted	None
PC	Deletes the property from the PC	None
SPDEL_1	Delete from PC, with side effects	MUST update <b>PidTagSubject</b> and/or <b>PidTagNormalizedSubject</b>
SPDEL_2	Delete from PC, with side effects	MUST update <b>PidTagBody</b> , <b>PidTagRtfCompressed</b> , <b>PidTagRtfInSync</b> , <b>PidTagHtml</b> , and <b>PidTagBodyHtml</b> (ANSI PST only)
SPDEL_3	Delete from PC, with	MAY need to also update <b>PidTagRtfSyncBodyCrc</b> , <b>PidTagRtfSyncBodyCount</b> , <b>PidTagRtfSyncBodyTag</b> ,

Mnemonic	Action	Side Effects
	side effects	<b>PidTagRtfSyncPrefixCount</b> , and/or <b>PidTagRtfSyncTrailingCount</b>
SPDEL_4	Succeeds, but does not actually delete the property	None
SPDEL_5	Delete, with side effects	<b>PidTagConversationId</b>

#### 2.5.3.4 Interpreting the List Behavior Column

The last column in the calculated property table indicates that visibility of each property when various operations to retrieve or otherwise list the property are invoked. There are three possible List behaviors for each property, which are explained in the following table.

Behavior	Description
ALWAYS	The property is ALWAYS included in an enumerate properties call.
ALLOW	This property is only included in an enumerate properties call if the property already exists in the underlying PC.
BASED	This property is included only if the property indicated in the Base Tag column exists in the PC.
BODY	This property is included only if at least one of the Message object body properties ( <b>PidTagRtfCompressed</b> , <b>PidTagBody</b> , <b>PidTagBodyHtml</b> or <b>PidTagHtml</b> ) exists in the PC.
NEVER	This property is never included in an enumerate properties call.

Note that the List behavior only dictates the visibility of a calculated property during a call to enumerate all the properties of an object. A property with a List Behavior of NEVER can still be retrieved and even modified (according to its Get / Set and Delete rules).

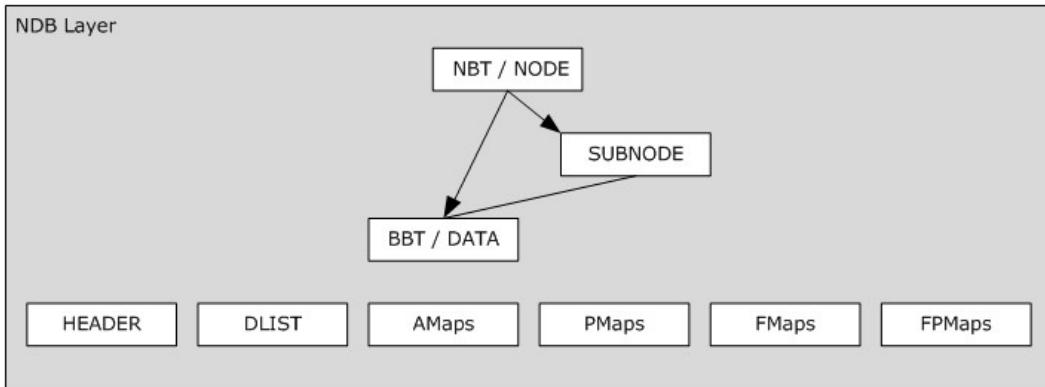

## 2.6 Maintaining Data Integrity

The following section outlines a series of considerations for implementations that intend to modify the contents of a PST.

This section specifies a set of implementation considerations to maintain PST file integrity while modifying its contents and to ensure the modified PST continues to be recognized and accessible by other implementations of this protocol. Specific algorithms are not discussed in this section.

### 2.6.1 NDB Layer

The NDB Layer, for the purpose of discussion in this section, consists of two portions: an infrastructure portion, and the NDB portion, as shown in the following diagram.

**Figure 16: NDB Layer**

The infrastructure portion contains the various elements in the PST that maintain the lowest-level information, which includes: the PST header and the allocation metadata pages (that is, AMaps, PMaps, FMaps, FPMaps, and the DList). Together these entities form the underlying infrastructure that represent the metadata and state on which the proper functioning of the PST relies. The header and the allocation metadata pages are the only entities in the PST that are ever modified in-place.

The NDB portion is the node database that includes the NBT and BBT, and all its associated operations. This section covers the various implementation considerations associated with the NDB Layer. To start, the following table illustrates the various entities that exist in the NDB Layer.

Entity	Required?	Instances	Remarks
PST HEADER	Y	1	The PST header MUST be maintained and up-to-date at all times .
AMap	Y	Many, Periodic	Authoritative source of all free/allocated space in the PST, MUST be maintained at all times.
PMap	Y	Many, Periodic	MUST exist in correct intervals for backward client compatibility. Implementations SHOULD NOT modify PMaps after they are created. < <a href="#">18</a> >
FMap	Y	Many, Periodic	MUST exist in correct intervals for backward client compatibility. Implementations SHOULD NOT modify FMaps after they are created. < <a href="#">19</a> >
FPMAP	Y	Many, Periodic	MUST exist in correct intervals for backward client compatibility. Implementations SHOULD NOT modify FPMaps after they are created. < <a href="#">20</a> >
DList	N	1	SHOULD exist and if valid, SHOULD be used as an optimization feature to locate sparsely-allocated AMaps. < <a href="#">21</a> >
NBT	Y	1	The NBT MUST be maintained and up-to-date at all times.
BBT	Y	1	The BBT MUST be maintained and up-to-date at all times.

### 2.6.1.1 Basic Operations

The following sections describe the most common operations performed at the NDB Layer, and specific implementation considerations.

### 2.6.1.1.1 Allocating Space from the PST

Synopsis: Allocating space directly from the PST file for higher-level operations.

Requirement Level	Actions
Required:	<ul style="list-style-type: none"><li>▪ MUST check the <b>fAMapValid</b> value in the ROOT structure before proceeding (section <a href="#">2.6.1.3.8</a>).</li><li>▪ Each allocation MUST NOT exceed 8KB (8192 bytes) in size.</li><li>▪ The corresponding AMap MUST be updated to reflect the allocation (section <a href="#">2.2.2.7.2</a>).</li><li>▪ The <b>cbAMapFree</b> and <b>cbPMapFree</b> fields in the HEADER.ROOT structure MUST be updated to reflect the allocation.</li></ul>
Recommended:	<ul style="list-style-type: none"><li>▪ Use the DList, PMap, FMap, FPMMap as optimizations where appropriate.</li></ul>
Optional:	<ul style="list-style-type: none"><li>▪ Update the DList.</li><li>▪ Update the PMap, FMap, FPMMap where appropriate.</li></ul>

Possible Side Effects:

Scenario	Impact
Free slot of required size not found	The PST File needs to grow. Refer to section <a href="#">2.6.1.1.2</a> for additional considerations.

### 2.6.1.1.2 Growing the PST File

Synopsis: Increasing the size of the PST file to create more space for allocation.

Requirement Level	Actions
Required:	<ul style="list-style-type: none"><li>▪ The PST file MUST grow at integer multiples of the number of bytes mapped by an AMap (that is, multiples of approximately 250KB)</li><li>▪ All new AMaps created MUST be properly initialized</li><li>▪ If needed, PMaps, FMaps, and FPMMaps MUST be created at the required intervals and properly initialized (section <a href="#">2.2.2.7</a>).</li><li>▪ The <b>ibFileEof</b>, <b>ibAMapLast</b>, <b>cbAMapFree</b> and <b>cbPMapFree</b> fields in the HEADER.ROOT structure MUST be updated to reflect the growth</li></ul>
Recommended:	None.
Optional:	<ul style="list-style-type: none"><li>▪ Update the DList</li></ul>

Possible Side Effects: None

#### 2.6.1.1.3 Freeing Space back to the PST

Synopsis: Freeing allocated space to the PST.

Requirement Level	Actions
Required:	<ul style="list-style-type: none"><li>▪ The corresponding AMap MUST be updated to reflect the freed page (section 2.2.2.7.2).</li><li>▪ The <b>cbAMapFree</b> and <b>cbPMapFree</b> fields in the HEADER.ROOT structure MUST be updated accordingly.</li></ul>
Recommended:	None.
Optional:	<ul style="list-style-type: none"><li>▪ Update the DList.</li><li>▪ Update the PMap, FMap, FPMMap where appropriate.</li></ul>

Possible Side Effects: None.

#### 2.6.1.1.4 Creating a Page

Synopsis: Allocating a new page and assigning an appropriate BID.

Requirement Level	Actions
Required:	<ul style="list-style-type: none"><li>▪ MUST check the <b>fAMapValid</b> value in the ROOT structure before proceeding (see section <a href="#">2.6.1.3.8</a>).</li><li>▪ Page allocations MUST be 512 bytes in size and aligned on a 512-byte boundary</li><li>▪ Allocate space for the page (section <a href="#">2.6.1.1.1</a>).</li><li>▪ The PAGETRAILER MUST be initialized (section <a href="#">2.2.2.7.1</a>).</li><li>▪ The BBT Reference Count for each data block MUST be initialized.</li><li>▪ The BBT MUST be updated to reflect the new data block(s).</li><li>▪ The <b>bidNextB</b> field in the HEADER.ROOT structure MUST be incremented.</li><li>▪ The <b>bidNextP</b> field in HEADER MUST also be incremented.</li></ul>
Recommended:	<ul style="list-style-type: none"><li>▪ Use the DList, PMap, FMap, FPMMap as optimizations where appropriate.</li></ul>
Optional:	<ul style="list-style-type: none"><li>▪ Update the DList.</li><li>▪ Update the PMap, FMap, FPMMap where appropriate.</li></ul>

Possible Side Effects:

Scenario	Impact
Free slot of required size not found	The PST File needs to grow. Refer to section <a href="#">2.6.1.1.2</a> for additional considerations.
BBT page too full	The BBT might need more levels and/or need to be balanced.

### 2.6.1.1.5 Creating a Block

Synopsis: Allocating a new data block and assigning an appropriate BID.

Requirement Level	Actions
Required:	<ul style="list-style-type: none"> <li>▪ MUST check the <b>fAMapValid</b> value in the ROOT structure before proceeding (section <a href="#">2.6.1.3.8</a>).</li> <li>▪ Block allocations MUST be integer multiples of 64 bytes in size and aligned on a 64-byte boundary. The allocation size MUST factor in the size of the extra BLOCKTRAILER.</li> <li>▪ Allocate space for the block (section <a href="#">2.6.1.1.1</a>).</li> <li>▪ Non-internal data blocks MUST be encoded according to HEADER.<b>bCryptMethod</b>.</li> <li>▪ The BBT Reference Count for each data block MUST be initialized.</li> <li>▪ The BBT MUST be updated to reflect the new data block(s).</li> <li>▪ The BLOCKTRAILER MUST be initialized, including the data CRC (section <a href="#">2.2.2.8.1</a>).</li> <li>▪ The <b>bidNextB</b> field in the HEADER.ROOT structure MUST be incremented.</li> </ul>
Recommended:	<ul style="list-style-type: none"> <li>▪ Use the DList, PMap, FMap, FPMMap as optimizations where appropriate.</li> </ul>
Optional:	<ul style="list-style-type: none"> <li>▪ Update the DList.</li> <li>▪ Update the PMap, FMap, FPMMap where appropriate.</li> </ul>

Possible Side Effects:

Scenario	Impact
Free slot of required size not found	The PST File needs to grow. Refer to section <a href="#">2.6.1.1.2</a> for additional considerations.
BBT page too full	The BBT might need more levels and/or need to be balanced.

### 2.6.1.1.6 Freeing Up a Page in the PST

Synopsis: Freeing an allocated page back to the PST file.

Requirement Level	Actions
Required:	<ul style="list-style-type: none"> <li>▪ Drop the reference count of the BID that corresponds to the page.</li> <li>▪ If the reference count drops to less than 2, then free the BID (section 2.6.1.1.3).</li> </ul>
Recommended:	<ul style="list-style-type: none"> <li>▪ Validate the PAGETRAILER to make sure the page is valid (section 2.2.2.7.1).</li> </ul>
Optional:	None.

Possible Side Effects: None.

#### 2.6.1.1.7 Dropping the Reference Count of a Block

Synopsis: Dropping the reference count of an allocated block, and freeing back to the PST it if the reference count drops to one or less.

Requirement Level	Actions
Required:	<ul style="list-style-type: none"> <li>▪ Drop the reference count of the BID associated with the data block.</li> <li>▪ If the reference count drops to less than 2, then free the BID (section 2.6.1.1.3).</li> </ul>
Recommended:	<ul style="list-style-type: none"> <li>▪ Validate the BLOCKTRAILER to make sure the block is valid (section 2.2.2.8.1).</li> </ul>
Optional:	None.

Possible Side Effects: None.

#### 2.6.1.1.8 Modifying a Page

Synopsis: Modifying the contents of a page.

Requirement Level	Actions
Required:	<ul style="list-style-type: none"> <li>▪ MUST check the <b>fAMapValid</b> value in the ROOT structure before proceeding (see section 2.6.1.3.8).</li> <li>▪ Create a new page for the modifications (section 2.6.1.1.4).</li> <li>▪ Replace references to the old page BID with the new page BID.</li> <li>▪ Free the old page (section 2.6.1.1.6).</li> </ul>
Recommended:	None.
Optional:	None.

Possible Side Effects:

Scenario	Impact
Free slot of required size not found	The PST File needs to grow. Refer to section 2.6.1.1.2 for additional considerations.
Higher-level pages reference this page	Higher-level pages MUST be recursively modified using the same mechanism.

### 2.6.1.1.9 Modifying a Block

Synopsis: Modifying the contents of a block.

Requirement Level	Actions
Required:	<ul style="list-style-type: none"> <li>▪ MUST check the <b>fAMapValid</b> value in the ROOT structure before proceeding (see section 2.6.1.3.8).</li> <li>▪ Create a new block for the modified data (section 2.6.1.1.5).</li> <li>▪ Replace references to the old BID with the new BID, this requires cascading modifications to other referencing pages (section 2.6.1.1.8).</li> <li>▪ Drop the reference count of the old block (section 2.6.1.1.7).</li> </ul>
Recommended:	None.
Optional:	None.

Possible Side Effects:

Scenario	Impact
Free slot of required size not found	The PST File needs to grow. Refer to section 2.6.1.1.2 for additional considerations.
The block is referenced by a data tree	The XBLOCK and the data tree blocks that reference the XBLOCK MUST be recursively modified using the same mechanism.

### 2.6.1.2 NDB Operations

#### 2.6.1.2.1 Creating a New Node

Synopsis: Creating a new node with a data BLOB (see next section for adding a subnode).

Requirement Level	Actions
Required:	<ul style="list-style-type: none"> <li>▪ New data block(s) MUST be allocated to store the data (section 2.6.1.1.5).</li> <li>▪ The NBT MUST be updated to reflect the new node and associated BIDs (section 2.2.2.7.7.4).</li> </ul>

Requirement Level	Actions
	<ul style="list-style-type: none"> <li>The corresponding <b>rgnind[nidType]</b> field in the HEADER.ROOT structure MUST be incremented accordingly.</li> </ul>
Recommended:	<ul style="list-style-type: none"> <li>BTree pages SHOULD be maintained at under 90% capacity.</li> </ul>
Optional:	None..

Possible Side Effects:

Scenario	Impact
Not enough free space	The PST File needs to grow.
BBT page too full	The BBT might need more levels and/or need to be balanced.
NBT page too full	The NBT might need more levels and/or need to be balanced.
Data BLOB larger than 8KB	A data tree needs to be constructed to store the data BLOB.

### 2.6.1.2.2 Creating/Adding a Subnode Entry

Synopsis: Creating a subnode entry with a data BLOB and associates it with an existing node.

Requirement Level	Actions
Required:	<ul style="list-style-type: none"> <li>Create a new data block (section 2.6.1.1.5).</li> <li>Allocate an SLBLOCK, if one does not exist (section 2.6.1.1.5).</li> <li>Associate the SLBLOCK with nidSub of the containing node (NBT page needs to be modified).</li> <li>Create a new SLENTRY in the SLBLOCK and associate it with the data block.</li> </ul>
Recommended:	None.
Optional:	None.

Possible Side Effects:

Scenario	Impact
Not enough free space	The PST File needs to grow.
BBT page too full	The BBT might need more levels and/or need to be balanced.
SLBLOCK is full	The subnode BTree needs to grow in depth to accommodate new subnode entry.
Data BLOB larger than 8KB	A data tree needs to be constructed to store the data BLOB.

Remarks:

- NIDs for subnodes are internal and therefore NOT allocated from the **rgnid[nidType]** counter in the HEADER.

### 2.6.1.2.3 Modifying Node Data

Synopsis: Modifying the contents of the data BLOB of an existing node.

Requirement Level	Actions
Required:	<ul style="list-style-type: none"><li>▪ Create New data block(s) for the modified data (section 2.6.1.1.5).</li><li>▪ The NBT node entry MUST be updated with the new BID(s) (section 2.6.1.1.8).</li></ul>
Recommended:	<ul style="list-style-type: none"><li>▪ If the data is stored in a data tree, implementations are encouraged to add optimizations to only replace the specific blocks that have actually been modified.</li></ul>
Optional:	None.

Possible Side Effects:

Scenario	Impact
Not enough free space to store the new data BLOB	The PST File needs to grow.
BBT page too full	The BBT might need more levels and/or need to be balanced.
New data BLOB larger than 8KB	A data tree needs to be constructed to store the data BLOB.

Remarks:

- A new data block MUST always be allocated even if the new content is smaller than or equal to the old content in size. See section 2.6.1.3.1 for further explanation.

### 2.6.1.2.4 Duplicating the Contents of one Node to Another

Synopsis: Copying all the contents of an existing node to a new node, where the new node can be a top-level node or a subnode (for example, when a Message object is added to another Message object as an Attachment object). Both nodes end up referencing the same instance of the data block, and subnodes (that is, single-instancing).

Requirement Level	Actions
Required:	<ul style="list-style-type: none"><li>▪ The BBT Reference Count for <b>bidData</b> and <b>bidSub</b> of the existing node MUST be incremented.</li><li>▪ The NBT or SLBLOCK MUST be updated, depending on whether the target is a node or subnode, to reflect the new node, using the same <b>bidData</b> and <b>bidSub</b></li></ul>

Requirement Level	Actions
	<p>values as the existing node.</p> <ul style="list-style-type: none"> <li>▪ The corresponding <b>rgnind[nidType]</b> field in the HEADER.ROOT structure MUST be incremented.</li> </ul>
Recommended:	None.
Optional:	None.

Possible Side Effects:

Scenario	Impact
NBT page too full	The NBT might need more levels and/or need to be balanced.
The target is a subnode and the SLBLOCK is full	The subnode BTree needs to grow in depth to accommodate new subnode entry.

Remarks:

- If **bidData** points to a data tree, there is no need to recursively increment the reference count of its child data blocks.
- If the node contains a subnode, there is no need to recursively increment the reference count of its child data blocks.
- In many cases the existing node and new node have a different **nidParent**.

### 2.6.1.2.5 Modifying Subnode Entry Data

Synopsis: Modifying the data associated with a subnode entry. This is identical to modifying node data in section 2.6.1.2.3, except that the subnode entry is located using the subnode BTree of the containing node instead of looking up the NBT.

Requirement Level	Actions
Required:	<ul style="list-style-type: none"> <li>▪ Create new data block(s) for the modified data (section 2.6.1.1.5).</li> <li>▪ The corresponding SLBLOCK subnode entry MUST be updated with the new BID(s) (section 2.6.1.1.5).</li> <li>▪ Modify NBT pages that reference the subnode BTree (section 2.6.1.1.8).</li> </ul>
Recommended:	<ul style="list-style-type: none"> <li>▪ If the data is stored in a data tree, implementations are encouraged to add optimizations to only replace the specific blocks that have actually been modified.</li> </ul>
Optional:	None.

Possible Side Effects:

Scenario	Impact
Not enough free space to store the new data BLOB	The PST File needs to grow.
BBT page too full	The BBT might need more levels and/or need to be balanced.
New data BLOB larger than 8KB	A data tree needs to be constructed to store the data BLOB.
The SLBLOCK is full and a new subnode entry is added	The subnode BTTree needs to grow in depth to accommodate new subnode entry.

Remarks: See section 2.6.1.2.3.

#### 2.6.1.2.6 Deleting a Subnode

Synopsis: Deleting an existing subnode.

Requirement Level	Actions
Required:	<ul style="list-style-type: none"> <li>▪ The reference count for <b>bidData</b> and <b>bidSub</b> of each subnode entry MUST be dropped (section 2.6.1.1.7).</li> <li>▪ The corresponding subnode entry MUST be removed from the SLBLOCK of the containing node (section 2.6.1.1.9).</li> <li>▪ The reference count of the SLBLOCK MUST be dropped (section 2.6.1.1.7).</li> </ul>
Recommended:	None.
Optional:	None.

Possible Side Effects:

Scenario	Impact
Subnode contains subnodes	The reference counts of the <b>bidData</b> and <b>bidSub</b> for each of the Sub-subnodes MUST be dropped, which ensures the appropriate blocks are freed.

#### 2.6.1.2.7 Deleting a node

Synopsis: Deleting an existing node and its contents from the PST.

Requirement Level	Actions
Required:	<ul style="list-style-type: none"> <li>▪ The reference count for <b>bidData</b> MUST be dropped (section <a href="#">2.6.1.1.7</a>).</li> <li>▪ Reference count of <b>bidSub</b>, if exists, MUST be dropped (section <a href="#">2.6.1.1.7</a>).</li> <li>▪ The node MUST be removed from the NBT (section <a href="#">2.6.1.1.8</a>).</li> </ul>
Recommended:	None.
Optional:	None.

Possible Side Effects:

Scenario	Impact
The key of the Deleted entry is also a key value used in the parent index block	If the leaf block is not empty after the delete, then the index row in the parent index block MUST be updated to use the next key value in the leaf block. However, if the leaf block is empty, then the parent index row MUST be removed. In some cases (for example, the index block becomes empty as well) this can have cascading effects up the index path.

### 2.6.1.3 Special Considerations

The following is a list of special considerations while implementing a PST client.

#### 2.6.1.3.1 Immutability

This protocol treats the NDB as an immutable store. What this means is that, with the exception of the header and allocation metadata pages, the data in the NDB MUST NOT be modified in-place. Instead, a new copy of the data needs to be written at a new location, and then, when all references of the pre-existing data have been removed, the old data can be purged.

#### 2.6.1.3.2 Single-instance Storage

As seen in section 2.6.1.2.4, the NDB Layer supports single-instance storage by having reference counts associated with each data block. Additional references to the same BID can be held as multiple nodes hold references to the same BID. This, combined with the immutability of the NDB store, allows new versions of a particular modified copy to be persisted in a new BID while all the other un-modified copies continue to refer to the old data.

#### 2.6.1.3.3 Transactional Semantics

Higher-level messaging applications often require transactional semantics that allow independent views of the underlying data. For example, if two Message objects are opened and then one of them is modified, the other does not see the changes unless and until it is closed and re-opened.

Such semantics can be modeled over the NDB, because each Message object is represented by a node, which only contains a BID for the data block and optionally a subnode. Because the NDB is immutable, which means any modification to the underlying Message object MUST cause the BID to increase, by caching the BIDs when opening a Message object, an implementation can determine whether the underlying Message object had been modified since the Message object was opened.

By architecting the sequence of modifications to ensure that BIDs are only updated after all the underlying data is successfully written, an implementation can design a system that leaves little or no chance for a Message object to end up in an inconsistent state.

In addition, the **fAMapValid** flag in the ROOT structure can also be used to implement transactional semantics for a group of related operations that requires several allocations from the PST (that is, AMaps). See section [2.6.1.3.8](#) for further details.

#### 2.6.1.3.4 Backfilling

Backfilling is an allocation strategy designed to reclaim some of the free space in the PST methodically walking through the file from end to start, filling in empty spaces along the way as allocation requests come in. The backfilling process is initiated when the overall file utilization (that

is, free space to file size ratio) drops below a certain threshold. The threshold is not specified in the PST file and is up to the implementation of the PST client.

When a backfill is initiated, the DFL\_BACKFILL\_COMPLETE flag is cleared from the DList and the **ulCurrentPage** field in the DLISTPAGE is set to the index of the last AMap page of the PST. For subsequent allocations, the implementation SHOULD scan for free space backwards (that is, towards the beginning of the file). If space is found, then space is allocated from the AMap page indicated by **ulCurrentPage**. However, if that AMap page cannot service the allocation, then **ulCurrentPage** is updated with the index of the AMap page before the current page. The process repeats itself until the **ulCurrentPage** reaches the first AMap page, in which case the backfill has finished and the DFL\_BACKFILL\_COMPLETE flag is set in **bFlags**.

Note that backfilling is an optional optimization feature and is not required.[<22>](#)

#### 2.6.1.3.5 Internal Fragmentation and Locality of Reference

The immutable nature of the NDB means that any data that is modified from time to time is constantly being moved around in the file, because each modification requires a new allocation in the file. This also means that, as data is edited, small pockets of free space are created throughout the file when the original copy of the data is removed.

The allocation algorithm used by the NDB is very efficient in repurposing the small pockets of free space created when a block is edited. However this algorithm makes no attempt to keep related data together because the overall goal is to use space within the file as efficiently as possible.

The end result of this is that any NDB which is not completely static is very prone to internal fragmentation as edits are made. This is especially true of larger streams of data because they are comprised of many blocks, some of which are touched by edits and others of which are not. Those blocks touched by an edit move and those that aren't remain where they are, leading to more and more fragmentation as the different parts of the stream are edited at different times.

This tendency of a PST to fragment internally naturally lends to low locality of reference which means highly scattered read/write patterns. It is recommended that implementations design an appropriate access mechanism that minimizes the performance impact of fragmented data access.

#### 2.6.1.3.6 Caching

Modifications to NDB objects often require updates in several different areas of the PST file. For example, creating a new node requires, at a minimum, modifications to the HEADER, AMap, BBT, NBT and also writing data block(s). These modifications become more frequent and compound quickly as higher-level operations are involved (such as moving a Folder object with sub-Folder objects). Often, the same object is modified several times within a single high-level operation.

Caching is a very efficient way to reduce the cost of disk I/O by eliminating unnecessary write-through for objects that are constantly being updated, such as the HEADER, AMaps, NBT / BBT pages, and so on). Performance enhancements can be achieved by implementing page and/or data block caching mechanisms.

#### 2.6.1.3.7 Concurrent Access

While there is no technical limitation preventing an implementation from offering a shared or concurrent model for accessing the PST, implementations SHOULD NOT allow concurrent access.

### 2.6.1.3.8 Crash Recovery and AMap Rebuilding

The **fAMapValid** flag in the ROOT structure is used to indicate whether the AMaps in the PST file are in a known-valid state. In general, this flag is set to one of the two valid states described in section [2.2.2.5](#).

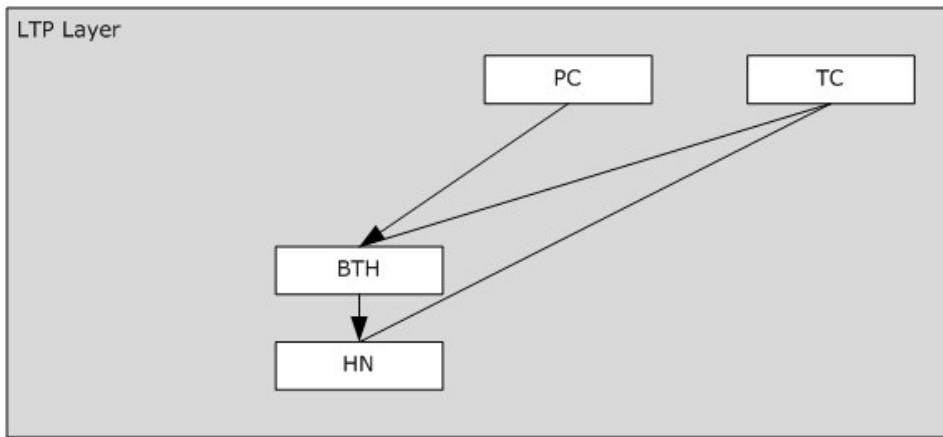

However, at the beginning of any operation that either allocates or frees space in the PST file, implementations set the **fAMapValid** value to INVALID\_AMAP, which signifies that the AMaps (and also PMaps, FMaps, and FPMaps, for that matter) cannot be trusted. When the operation is complete, this value is set back to the valid state. In the event where the PST file is abnormally closed before the operation is finished, it is likely that **fAMapValid** was never restored back to the valid state. In that case, the PST file MUST go through a very expensive recovery operation the next time an attempt to allocate file space is made.

This recovery phase, called an "AMap rebuild", involves first marking all the AMaps as "free", and then walking the NBT and BBT to mark pages and blocks as "allocated" in the appropriate map pages as they appear. The rebuild process also ensures that all space occupied by the AMaps, PMaps, FMaps and FPMaps are properly marked as allocated.

Implementations are NOT required to implement AMap Rebuild algorithms, but MUST first check the **fAMapValid** value before manipulating the AMaps in any way. If the **fAMapValid** value is set to invalid, implementations that do not implement AMap Rebuild algorithms MUST NOT modify the PST file in any way. Read-only implementations, however, MAY ignore the **fAMapValid** value.

## 2.6.2 LTP Layer

The LTP Layer provides higher-level semantics that abstract the primitive node-based operations. The following diagram graphically illustrates the various structures provided by the LTP Layer.

**Figure 17: LTP Layer**

The following sections describe the most common operations performed at the LTP Layer, and specific implementation considerations.

## 2.6.2.1 HN Operations

### 2.6.2.1.1 Creating a HN

Synopsis: Creating a heap node. This is identical to creating a node in section 2.6.1.2.1, with a data BLOB that contains properly-formatted HNHDR and HNPAGEMAP structures.

Requirement Level	Actions
Required:	<ul style="list-style-type: none"><li>▪ See requirements for section 2.6.1.2.1.</li><li>▪ The HNHDR and HNPAGEMAP structures MUST be properly initialized (section 2.3.1).</li></ul>
Recommended:	None.
Optional:	None.

Possible Side Effects: See section 2.6.1.2.1.

### 2.6.2.1.2 Allocating from the HN

Synopsis: Allocates space out of the heap node. This is an extended case of modifying node data in section [2.6.1.2.3](#).

Requirement Level	Actions
Required:	<ul style="list-style-type: none"><li>▪ See requirements for section <a href="#">2.6.1.2.3</a>.</li><li>▪ A heap allocation MUST fit within a single block.</li><li>▪ Maximum size of a heap allocation is 3580 bytes.</li><li>▪ HNPAGEMAP for any modified heap block MUST be maintained (section <a href="#">2.3.1.5</a>).</li></ul>
Recommended:	<ul style="list-style-type: none"><li>▪ Update the Fill Level Map that corresponds to the modified block (HNs with a data tree).</li></ul>
Optional:	None.

Possible Side Effects: See section [2.6.1.2.3](#).

Remarks:

- When a HN no longer fits within a single data block, a data tree is created to span multiple data blocks. When adding new data blocks, implementers MUST use the correct block header format (that is, HNHDR, HNPAGEHDR or HNBITMAPHDR). Refer to section [2.3.1.6](#) for details.

### 2.6.2.1.3 Freeing an Allocation

Synopsis: Freeing an allocated slot in the heap node. This is an extended case of modifying node data in section [2.6.1.2.3](#).

Requirement Level	Actions
Required:	<ul style="list-style-type: none"> <li>▪ An existing HN (section <a href="#">2.6.2.1.1</a>).</li> <li>▪ See requirements for section <a href="#">2.6.1.2.3</a>.</li> <li>▪ If the freed allocation leaves a gap between allocations, the latter entries MUST be moved up to fill in the gap.</li> <li>▪ The <b>rgibAlloc</b> field of HNPAGEMAP MUST also be updated to reflect the new allocation offsets.</li> <li>▪ Update the Fill Level Map that corresponds to the freed space (HNs with a data tree) (section <a href="#">2.3.1.2</a> through section <a href="#">2.3.1.4</a>).</li> </ul>
Recommended:	None.
Optional:	None.

Possible Side Effects: See section [2.6.1.2.3](#).

Remarks:

- Because the HNPAGEMAP uses the starting offset of the next allocation (or the end of the allocations) to determine the size of the current allocation, any gaps in the allocated heap MUST be moved up to keep the data tightly packed. The **rgibAlloc** array also needs to be adjusted for the relocation of any subsequent entries.

#### 2.6.2.1.4 Deleting a HN

Synopsis: Deleting a heap node. This is identical to Deleting a node in section 2.6.1.2.7.

Requirement Level	Actions
Required:	<ul style="list-style-type: none"> <li>▪ See requirements for section 2.6.1.2.7.</li> </ul>
Recommended:	None.
Optional:	None.

Possible Side Effects: See section 2.6.1.2.7.

#### 2.6.2.2 BTH Operations

##### 2.6.2.2.1 Creating a BTH

Synopsis: Creating a new BTree-on-Heap. This is analogous to making a few allocations from the HN for the BTH-related structures.

Requirement Level	Actions
Required:	<ul style="list-style-type: none"> <li>▪ An existing HN (section 2.6.2.1.1).</li> <li>▪ The BTHEADER MUST be allocated from the HN (section 2.6.2.1.2), and properly initialized (section 2.3.2.1).</li> </ul>
Recommended:	None.
Optional:	None.

Possible Side Effects: See section 2.6.2.1.1 and 2.6.2.1.2.

### 2.6.2.2.2 Inserting into the BTH

Synopsis: Inserting a new entry into the BTH. This consists of modifying contents of the existing HN allocations, and possibly making new allocations to grow the BTH.

Requirement Level	Actions
Required:	<ul style="list-style-type: none"> <li>▪ An existing BTH (section 2.6.2.2.1).</li> <li>▪ A new HN allocation is made for the new data (section 2.6.2.1.2).</li> <li>▪ A new BTH record is created for the new item and inserted into the corresponding BTH structure (section 2.6.2.2.3) .</li> </ul>
Recommended:	<ul style="list-style-type: none"> <li>▪ BTH index and leaf blocks SHOULD be maintained at under 90% capacity.</li> </ul>
Optional:	None.

Possible Side Effects:

Scenario	Impact
BTM index / leaf block Full	The index / leaf block needs to be split and a new index level created. Portions of the BTTree MUST be re-balanced.

Remarks:

- To clarify the terminology, the word "block" referenced in "index / leaf block" actually refers to a HN allocation instead of an actual data block in the BBT.
- The size of an index or leaf block for a BTH is 3580 bytes. The number of index / leaf entries that can fit into each block depends on the size of the index and data items.

### 2.6.2.2.3 Modifying contents of a BTH Entry

Synopsis: Modifying contents of a BTH entry. This refers to modifying the data value of an existing BTH entry. In essence, this is a particular case of modifying node data in section 2.6.1.2.3.

Requirement Level	Actions
Required:	<ul style="list-style-type: none"> <li>▪ An existing BTH (section 2.6.2.2.1).</li> <li>▪ See requirements for section 2.6.1.2.3.</li> </ul>
Recommended:	None.
Optional:	None.

Possible Side Effects: See section 2.6.1.2.3.

Remarks: See section 2.6.1.2.3.

#### 2.6.2.2.4 Deleting a BTH Entry

Synopsis: Deleting an entry from a BTH is a particular case of modifying node data in section [2.6.1.2.3](#).

Requirement Level	Actions
Required:	<ul style="list-style-type: none"> <li>▪ See requirements for section <a href="#">2.6.1.2.3</a>.</li> <li>▪ The BTH entry MUST be deleted from the corresponding BTH structure (section <a href="#">2.3.2.3</a>).</li> </ul>
Recommended:	None.
Optional:	None.

Possible Side Effects:

Scenario	Impact
The key of the Deleted entry is also a key value used in the parent index block.	If the leaf block is not empty after the delete, then the index row in the parent index block MUST be updated to use the next key value in the leaf block. However, if the leaf block is empty, then the parent index row MUST be removed. In some cases (for example, the index block becomes empty as well) this can have cascading effects up the index path.
	Also see section <a href="#">2.6.1.2.3</a> .

Remarks: See section 3.1.2.3.

#### 2.6.2.2.5 Deleting a BTH

Synopsis: Deleting a BTH. This is identical to deleting a series of HN allocations in section 2.6.2.1.3.

Requirement Level	Actions
Required:	<ul style="list-style-type: none"> <li>▪ Starting from the HID of the BTH header, walk down all the BTH entry records (recursively if needed) and free all the HN allocations associated with the BTH</li> </ul>

Requirement Level	Actions
	<p>(section 2.6.2.1.3).</p> <ul style="list-style-type: none"> <li>▪ Once all the BTH entries are freed, free the BTH header (section 2.6.2.1.3).</li> </ul>
Recommended:	None.
Optional:	None.

Possible Side Effects: See section 2.6.2.1.3.

Remarks: See section 2.6.2.1.3.

### 2.6.2.3 PC Operations

#### 2.6.2.3.1 Creating a PC

Synopsis: Creating a Property Context. This is a special case of creating a BTH in section 2.6.2.2.1.

Requirement Level	Actions
Required:	<ul style="list-style-type: none"> <li>▪ See requirements for section 2.6.2.2.1.</li> <li>▪ Set the <b>hidUserRoot</b> to the HID of the BTH header (section 2.3.2.1).</li> <li>▪ The key size of the underlying BTH MUST be 2 bytes (section 2.3.3.3).</li> <li>▪ The data size of the underlying BTH MUST be 6 bytes (section 2.3.3.3).</li> </ul>
Recommended:	None.
Optional:	None.

Possible Side Effects: See section 2.6.2.2.1.

#### 2.6.2.3.2 Inserting into the PC

Synopsis: Inserting properties into the Property Context. This is very similar to inserting into the BTH in section [2.6.2.2.2](#), except that data that is larger than 4 bytes in size are stored in a separate HN allocation or in the subnode instead.

Requirement Level	Actions
Required:	<ul style="list-style-type: none"> <li>▪ An existing PC (section <a href="#">2.6.2.3.1</a>).</li> <li>▪ See requirements for section <a href="#">2.6.2.2.2</a>.</li> </ul>
Recommended:	None.
Optional:	None.

Possible Side Effects: See section and [2.6.2.2.2](#) and [2.6.2.3.1](#) (if applicable).

Remarks:

- If the data is variable-size but less than or equal to 3580 bytes, then the data is stored in a separate HN allocation. The HID of the allocation is stored in the **dwValueHnid** field for the PC BTH record (section [2.3.3.3](#)).
- If the data is variable-size and more than 3580 bytes, then the data is stored in a separate subnode entry. The subnode NID is stored in the **dwValueHnid** field of the PC BTH record (section [2.3.3.3](#)).
- Because a HID is a special NID with NID\_TYPE of NID\_TYPE\_HID, HIDs and subnode NIDs values never collide, implementations can easily determine if **dwValueHnid** points to a HID or a subnode (section [2.2.2.1](#)).

#### 2.6.2.3.3 Modifying the Value of a Property

Synopsis: Modifying the value of an existing property in the Property Context. This is similar to modifying contents of a BTH entry in section [2.6.2.2.3](#), except when the data is stored in a separate HN allocation (section [2.6.1.2.3](#)) or in the subnode (section [2.6.1.2.5](#)).

Requirement Level	Actions
Required:	<ul style="list-style-type: none"><li>▪ An existing PC (section <a href="#">2.6.2.3.1</a>).</li><li>▪ See section <a href="#">2.6.2.2.3</a>, <a href="#">2.6.1.2.3</a>, and <a href="#">2.6.1.2.5</a> (if applicable).</li></ul>
Recommended:	None.
Optional:	None.

Possible Side Effects: See sections [2.6.2.3.1](#), [2.6.2.2.3](#), [2.6.1.2.3](#), and [2.6.1.2.5](#), where applicable.

Remarks: See sections [2.6.2.3.1](#), [2.6.2.2.3](#), [2.6.1.2.3](#), and [2.6.1.2.5](#), where applicable.

#### 2.6.2.3.4 Deleting a Property

Synopsis: Deleting an existing property from a Property Context. This is similar to Deleting a BTH entry in section [2.6.2.2.4](#), except when the data is stored in a separate HN allocation (section [2.6.2.1.3](#)) or in the subnode (section [2.6.1.2.6](#)).

Requirement Level	Actions
Required:	<ul style="list-style-type: none"><li>▪ An existing PC (section <a href="#">2.6.2.3.1</a>).</li><li>▪ See section <a href="#">2.6.2.2.4</a>, <a href="#">2.6.2.1.3</a> and <a href="#">2.6.1.2.6</a> (if applicable).</li></ul>
Recommended:	None.
Optional:	None.

Possible Side Effects: See sections [2.6.2.3.1](#), [2.6.2.2.4](#), [2.6.2.1.3](#), and [2.6.1.2.6](#), where applicable.

Remarks: See sections [2.6.2.3.1](#), [2.6.2.2.4](#), [2.6.2.1.3](#), and [2.6.1.2.6](#), where applicable.

### 2.6.2.3.5 Deleting a PC

Synopsis: Deletes an existing Property Context altogether. This is identical to Deleting a node in section 2.6.1.2.7.

Requirement Level	Actions
Required:	<ul style="list-style-type: none"><li>▪ See requirements for section 2.6.1.2.7.</li></ul>
Recommended:	None.
Optional:	None.

Possible Side Effects: See section 2.6.1.2.7.

Remarks: See section 2.6.1.2.7.

### 2.6.2.4 TC Operations

#### 2.6.2.4.1 Creating a TC

Synopsis: Creating a Table Context. This involves creating a heap node with specialized contents (section [2.6.2.1.1](#)), and an embedded BTH within the HN (section [2.6.2.2.1](#)).

Requirement Level	Actions
Required:	<ul style="list-style-type: none"><li>▪ See section <a href="#">2.6.2.1.1</a> and <a href="#">2.6.2.2.1</a>.</li><li>▪ The TCINFO (section <a href="#">2.3.4.1</a>) and <b>TCOLDESC</b> (section <a href="#">2.3.4.2</a>) structures MUST be properly initialized.</li><li>▪ The embedded BTH key and data fields MUST be set up according to the TCROWID structure (see section <a href="#">2.3.4.3.1</a>).</li></ul>
Recommended:	None.
Optional:	None.

Possible Side Effects: See section [2.6.2.1.1](#) and [2.6.2.2.1](#).

Remarks:

- When setting up the **TCOLDESC** structures, special care MUST be given when assigning the **iBit** fields to ensure the proper ordering of the columns based on the column data size (section [2.3.4.2](#)).
- Also refer to section [2.3.4.2](#) for the rules regarding setting the **cbData** field of **TCOLDESC**, noting the use of HNIDs for variable-size data or fixed-size data that exceeds 8 bytes.

#### **2.6.2.4.2 Inserting into the TC**

Synopsis: Inserting a row into the Table Context. This is analogous to Inserting an entry into the embedded BTH (section [2.6.2.2.2](#)). If the data is variable-size or exceeds 8 bytes, then the data is either stored in a separate HN allocation (section [2.6.2.1.2](#)), or in the subnode ([2.6.1.2.2](#)).

Requirement Level	Actions
Required:	<ul style="list-style-type: none"><li>▪ An existing TC (section <a href="#">2.6.2.4.1</a>).</li><li>▪ See requirements for section <a href="#">2.6.2.2.2</a>, <a href="#">2.6.2.1.2</a>, and <a href="#">2.6.1.2.2</a> (if applicable).</li><li>▪ The row data record (section <a href="#">2.3.4.4.1</a>) MUST be properly formatted and appended to the end of the existing Row Matrix.</li><li>▪ A properly-formatted TCROWID structure (see section <a href="#">2.3.4.3.1</a>) that corresponds to the row data record MUST be inserted into the embedded BTH.</li></ul>
Recommended:	None.
Optional:	None.

Possible Side Effects: See sections [2.6.2.4.1](#), [2.6.2.2.2](#), [2.6.2.1.2](#), and [2.6.1.2.2](#), where applicable.

Remarks:

- If the data is variable-size but less than or equal to 3580 bytes, then the data is stored in a separate HN allocation. The HID of the allocation is stored in the corresponding 4-byte data slot for the TC row data record (section [2.3.4.4.1](#)).
- If the data is variable-size and more than 3580 bytes, then the data is stored in a separate subnode entry. The subnode NID is stored in the corresponding 4-byte data slot in the TC row data record (section [2.3.4.4.1](#)).
- If the data is fixed-size and more than 8 bytes in size, then the data is stored in a separate HN allocation.
- Because a HID is a special NID with NID\_TYPE of NID\_TYPE\_HID, HIDs and subnode NIDs values never collide, implementations can easily determine if a data slot points to a HID or a subnode (section [2.2.2.1](#)).
- Also see sections [2.6.2.4.1](#), [2.6.2.2.2](#), [2.6.2.1.2](#), and [2.6.1.2.2](#), where applicable.

#### **2.6.2.4.3 Modifying contents of a Table Row**

Synopsis: Modifying the contents of a Table Row. This refers to changing the value of a column in a particular Table Row. This involves re-allocating from the HN, or modifying subnode entry data.

Requirement Level	Actions
Required:	<ul style="list-style-type: none"><li>▪ An existing TC (section 2.6.2.4.1).</li><li>▪ If the Row Matrix is in a HN, then see requirements for sections 2.6.2.1.2 and</li></ul>

Requirement Level	Actions
	<p>2.6.2.1.3.</p> <ul style="list-style-type: none"> <li>▪ If the Row Matrix is in a subnode entry, then see requirements for section 2.6.1.2.5.</li> </ul>
Recommended:	None.
Optional:	None.

Possible Side Effects: See sections 2.6.2.4.1, 2.6.2.1.2, 2.6.2.1.3, and 2.6.1.2.5, where applicable.

Remarks: See sections 2.6.2.4.1, 2.6.2.1.2, 2.6.2.1.3, and 2.6.1.2.5, where applicable.

#### 2.6.2.4.4 Adding a Column

Synopsis: Adding a column to a TC. This involves modifying the TCINFO, adding a new column definition to the **TCOLDESC** array, as well as widening every row of the Row Matrix to add a new data slot (and also widen the CEB array, if it runs out of unused bits). This involves allocating and freeing HN entries, and modifying subnode data, if the Row Matrix is stored in a subnode.

Requirement Level	Actions
Required:	<ul style="list-style-type: none"> <li>▪ An existing TC (section 2.6.2.4.1).</li> <li>▪ See requirements for sections 2.6.2.1.2, 2.6.2.1.3, and 2.6.1.2.5 (if applicable).</li> <li>▪ The TCINFO (section 2.3.4.1) MUST be updated to account for the new column.</li> <li>▪ A new <b>TCOLDESC</b> structure (section 2.3.4.2) MUST be added for the new column.</li> <li>▪ Each row in the Row Matrix needs to be widened to add an appropriate data slot for the new column.</li> <li>▪ If the CEB runs out of unused bits, then the CEB for each row MUST grow to accommodate the new column.</li> <li>▪ The CEB for each row MUST also be updated to indicate that the new column is "non-existent".</li> </ul>
Recommended:	None.
Optional:	None.

Possible Side Effects: See sections 32.6.2.4.1, 2.6.2.1.2, 2.6.2.1.3, and 2.6.1.2.5, where applicable.

Remarks:

- When setting up the new **TCOLDESC** structure, special care MUST be given when assigning the **iBit** fields to ensure the proper ordering of the columns based on the column data size (section 2.3.4.2). It is also important to re-assign the **iBit** fields of any other **TCOLDESC** structure that is shifted as a result of inserting the new column.

- Also refer to section 2.3.4.2 for the rules regarding setting the **cbData** field of **TCOLDESC**, noting the use of HNIDs for variable-size data or fixed-size data that exceeds 8 bytes.

#### 2.6.2.4.5 Deleting the value of a Column

Synopsis: Deleting the value of a column refers to setting the value of a column in a particular Table Row as "non-existent". This is done by setting the Cell Existence bit (CEB) that corresponds to that column in the row data to "0". This is a particular case of modifying contents of a Table Row.

Requirement Level	Actions
Required:	An existing TC (section <a href="#">2.6.2.4.1</a> ). See section <a href="#">2.6.2.4.3</a> .
Recommended:	None.
Optional:	None.

Possible Side Effects: See sections [2.6.2.4.1](#) and [2.6.2.4.3](#).

#### 2.6.2.4.6 Deleting a Column

Synopsis: Deleting an existing column in a Table Context.

Remarks:

- Implementations SHOULD NOT delete existing columns in a Table Context.

#### 2.6.2.4.7 Deleting a Row

Synopsis: Deleting an existing Row from a Table Context. This involves Deleting an entry from the embedded BTH (section 2.6.2.2.4) and modifying other BTH entry values (section 2.6.2.2.3), and re-allocating HN entries (sections 2.6.2.1.2, 2.6.2.1.3) or modifying subnode entry data (section 2.6.1.2.5), depending where the Row Matrix is stored.

Requirement Level	Actions
Required:	<ul style="list-style-type: none"> <li>An existing TC (section 2.6.2.4.1).</li> <li>See requirements for sections 2.6.2.2.4, 2.6.2.2.3, 2.6.2.1.2, 2.6.2.1.3, and 2.6.1.2.5 (if applicable).</li> <li>Subsequent rows in the Row Matrix MUST be moved up to replace the gap caused by the deleted row.</li> <li>Some TCROWID entries in the embedded BTH MUST also be updated (specifically theRowIndex field) to account for the shifting of their row index (section 2.3.4.3.1).</li> </ul>
Recommended:	None.
Optional:	None.

Possible Side Effects: See sections 2.6.2.2.4, 2.6.2.2.3, 2.6.2.1.2, 2.6.2.1.3, and 2.6.1.2.5, where applicable.

#### 2.6.2.4.8 Deleting a TC

Synopsis: Deleting an existing Table Context altogether. This is identical to Deleting a node in section [2.6.1.2.7](#).

Requirement Level	Actions
Required:	<ul style="list-style-type: none"><li>▪ See requirements for section <a href="#">2.6.1.2.7</a>.</li></ul>
Recommended:	None.
Optional:	None.

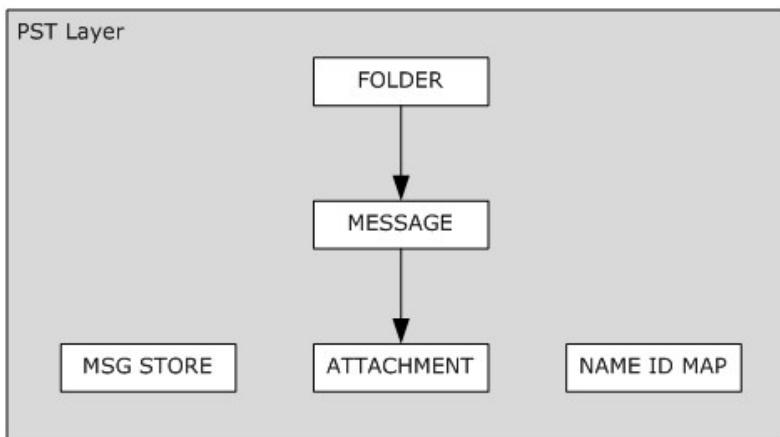

Possible Side Effects: See section [2.6.1.2.7](#).

Remarks:

- Because Table Contexts are rarely used in a stand-alone manner, special care MUST be taken to ensure that removing a TC does not cause higher-level entities to malfunction.

### 2.6.3 Messaging Layer

The Messaging Layer provides a Messaging-oriented interface that consists of concepts and objects that are consistent with structured storage models such as Folder objects, Message objects and Attachment objects. The following is a graphical illustration of the various structures exposed at the Messaging Layer.

**Figure 18: Messaging Layer**

The following sections describe the most common operations performed at the Messaging Layer, and specific implementation considerations.

#### 2.6.3.1 Message store Operations

##### 2.6.3.1.1 Creating the Message store

Synopsis: Creating the Message store. This is identical to creating a PC (section [2.6.2.3.1](#)) with a special NID, and setting a minimal set of properties (section [2.6.2.3.2](#)).

Requirement Level	Actions
Required:	<ul style="list-style-type: none"> <li>▪ Identical to section <a href="#">2.6.2.3.1</a> and <a href="#">2.6.2.3.2</a>.</li> <li>▪ NID MUST be NID_MESSAGE_STORE.</li> <li>▪ See minimal set of required properties in section <a href="#">2.4.3.1</a>.</li> </ul>
Recommended:	None.
Optional:	None.

Possible Side Effects: See section [2.6.2.3.1](#) and [2.6.2.3.2](#).

Remarks:

- Exactly one Message store MUST exist in a PST file.

### 2.6.3.1.2 Modifying Properties of the Message store

Synopsis: Modifying properties of the Message store. This refers to the adding, changing and deleting of properties to/from the Message store PC, which map directly to sections [2.6.2.3.2](#), [2.6.2.3.3](#) and [2.6.2.3.4](#).

Requirement Level	Actions
Required:	<ul style="list-style-type: none"> <li>▪ An existing Message store (section <a href="#">2.6.3.1.1</a>).</li> <li>▪ See sections <a href="#">2.6.2.3.2</a>, <a href="#">2.6.2.3.3</a> and <a href="#">2.6.2.3.4</a>, where applicable.</li> </ul>
Recommended:	None.
Optional:	None.

Possible Side Effects: See sections [2.6.2.3.2](#), [2.6.2.3.3](#) and [2.6.2.3.4](#), where applicable.

### 2.6.3.2 Folder object Operations

#### 2.6.3.2.1 Creating a Folder object

Synopsis: Creating a Folder object. This is equivalent to creating one PC with a minimal set of properties, and three TCs.

Requirement Level	Actions
Required:	<ul style="list-style-type: none"> <li>▪ See sections <a href="#">2.6.2.3.1</a>, <a href="#">2.6.2.4.1</a>, <a href="#">2.6.2.3.2</a>.</li> <li>▪ All 4 entities (1 PC, 3 TCs) MUST exist to function properly.</li> <li>▪ All 4 entities MUST have the same <b>nidIndex</b>.</li> <li>▪ The PC MUST have NID_TYPE of NID_TYPE_NORMAL_FOLDER.</li> </ul>

Requirement Level	Actions
	<ul style="list-style-type: none"> <li>▪ The 3 TCs MUST have <b>nidType</b> of NID_TYPE_ASSOC_CONTENTS_TABLE, NID_TYPE_CONTENTS_TABLE and NID_TYPE_HIERARCHY_TABLE.</li> <li>▪ See minimal set of required Folder object PC properties in section <a href="#">2.4.4.1.1</a>.</li> <li>▪ See minimal set of required columns for the Hierarchy TC in section <a href="#">2.4.4.4.1</a>.</li> <li>▪ See minimal set of required columns for the Contents TC in section <a href="#">2.4.4.5.1</a>.</li> <li>▪ See minimal set of required columns for the FAI contents table TC in section <a href="#">2.4.4.6.1</a>.</li> <li>▪ MUST queue a properly-formatted SUD of type SUDT_FLD_ADD to the SMQ (section <a href="#">2.4.8.1</a>).</li> </ul>
Recommended:	None.
Optional:	None.

Possible Side Effects: See section [2.6.2.3.1](#), [2.6.2.4.1](#), and [2.6.2.3.2](#).

### 2.6.3.2.2 Modifying Properties of a Folder object

Synopsis: Modifying properties of the Folder object. This refers to the adding, changing and deleting of properties to/from the Folder object PC, which map directly to sections 3.2.3.2, 3.2.3.3 and 3.2.3.4.

Requirement Level	Actions
Required:	<ul style="list-style-type: none"> <li>▪ An existing Folder object (section 3.3.2.1).</li> <li>▪ See sections <a href="#">2.6.2.3.2</a>, <a href="#">2.6.2.3.3</a> and <a href="#">2.6.2.3.4</a>, where applicable.</li> <li>▪ MUST queue a properly-formatted SUD of type SUDT_FLD_MOD to the SMQ (section <a href="#">2.4.8.1</a>).</li> </ul>
Recommended:	None.
Optional:	None.

Possible Side Effects: See sections [2.6.2.3.2](#), [2.6.2.3.3](#) and [2.6.2.3.4](#), where applicable

Remarks:

- Some Folder object properties are also duplicated in the hierarchy TC of the parent Folder object (See section [2.4.4.4.1](#)). Implementations MUST pay special attention to any properties that are duplicated elsewhere to make sure all instances of the properties are properly updated.
- Certain Special calculated properties exist that do not map directly to externally-published properties and therefore MUST be converted, calculated or otherwise translated before persisting to or retrieving from the PST. A list of such special properties is found in section [2.5](#).

### 2.6.3.2.3 Adding a sub-Folder object

Synopsis: Adding a sub-Folder object to an existing Folder object. This involves creating a new Folder object, and then adding the new Folder object to the existing parent Folder object's hierarchy. Creating a Folder object is identical to section [2.6.3.2.1](#), and adding the new Folder object to the parent means adding a new row (section [2.6.2.4.2](#)) to the Hierarchy TC of the parent Folder object. Also, some of the properties in the parent Folder object (for example, folder count) need to be updated (section [2.6.3.2.2](#)).

Requirement Level	Actions
Required:	<ul style="list-style-type: none"><li>▪ An existing parent Folder object (section <a href="#">2.6.3.2.1</a>).</li><li>▪ See sections <a href="#">2.6.3.2.1</a>, <a href="#">2.6.2.4.2</a>.</li><li>▪ <b>nidParent</b> of the new Folder object's NBT entry MUST be set to the NID of the parent Folder object (section <a href="#">2.2.2.7.7.4</a>).</li><li>▪ Parent properties MUST be updated to reflect new child Folder object (section <a href="#">2.6.3.2.2</a>).</li><li>▪ MUST queue a properly-formatted SUD of type SUDT_FLD_ADD for the sub-Folder object to the SMQ (section <a href="#">2.4.8.1</a>).</li></ul>
Recommended:	None.
Optional:	None.

Possible Side Effects: See sections [2.6.3.2.1](#), [2.6.2.4.2](#) and [2.6.3.2.2](#).

### 2.6.3.2.4 Moving a Folder object

Synopsis: Moving a Folder object refers to moving a child Folder object from its parent Folder object to another Folder object. This involves deleting the child Folder object row from the old parent's Hierarchy TC (section [2.6.2.4.7](#)), and adding it to the new parent's Hierarchy TC (section [2.6.2.4.2](#)). Also, some properties of both Folder object PCs (for example, folder count) need to be updated (section [2.6.3.2.2](#)).

Requirement Level	Actions
Required:	<ul style="list-style-type: none"><li>▪ An existing Folder object (section <a href="#">2.6.3.2.1</a>).</li><li>▪ An existing new parent Folder object (section <a href="#">2.6.3.2.1</a>).</li><li>▪ See sections <a href="#">2.6.2.4.7</a>, <a href="#">2.6.2.4.2</a>.</li><li>▪ <b>nidParent</b> of the moved Folder object's NBT entry MUST be set to the NID of the new parent Folder object (section <a href="#">2.2.2.7.7.4</a>).</li><li>▪ Old and new parent Folder object properties MUST be updated accordingly (section <a href="#">2.6.3.2.2</a>).</li><li>▪ MUST queue a properly-formatted SUD of type SUDT_FLD_MOV to the SMQ (section <a href="#">2.4.8.1</a>).</li></ul>

Requirement Level	Actions
Recommended:	None.
Optional:	None.

Possible Side Effects: See sections [2.6.3.2.1](#), [2.6.2.4.7](#), [2.6.2.4.2](#) and [2.6.3.2.2](#).

### 2.6.3.2.5 Copying a Folder object

Synopsis: Copying an existing Folder object to a new parent Folder object. This involves creating a new Folder object PC for the new Folder object and populating some properties (section [2.6.2.3.1](#) and [2.6.2.3.2](#)), followed by duplicating each of the 3 Folder object TC nodes of the original Folder object to new top-level nodes for the new Folder object (section [2.6.1.2.4](#)). Also the new Folder object needs to be added to the existing target Folder object hierarchy, which requires adding a new row (section [2.6.2.4.2](#)) to the Hierarchy TC of the target Folder object. Also, some of the properties in the target Folder object (for example folder count) need to be updated (section [2.6.3.2.2](#)).

Requirement Level	Actions
Required:	<ul style="list-style-type: none"> <li>▪ An existing Folder object (section <a href="#">2.6.3.2.1</a>).</li> <li>▪ An existing target Folder object (section <a href="#">2.6.3.2.1</a>).</li> <li>▪ See sections <a href="#">2.6.2.3.1</a>, <a href="#">2.6.2.3.2</a>, <a href="#">2.6.1.2.4</a> and <a href="#">2.6.2.4.2</a>.</li> <li>▪ See minimal set of required Folder object PC properties in <a href="#">2.4.4.1.1</a>.</li> <li>▪ <b>nidParent</b> of the new Folder object PC's NBT entry MUST be set to the NID of the target Folder object (section <a href="#">2.2.2.7.7.4</a>).</li> <li>▪ Target Folder object properties MUST be updated accordingly (section <a href="#">2.6.3.2.2</a>).</li> <li>▪ MUST queue a properly-formatted SUD of type SUDT_FLD_ADD for the copied Folder object to the SMQ (section <a href="#">2.4.8.1</a>).</li> </ul>
Recommended:	None.
Optional:	None.

Possible Side Effects: See sections [2.6.3.2.1](#), [2.6.2.3.1](#), [2.6.2.3.2](#) [2.6.1.2.4](#), [2.6.2.4.2](#), and [2.6.3.2.2](#).

Remarks:

- The 3 TCs of the copied Folder object are single-instanced to the original Folder object, which allows the Folder object copying process to be efficient.

### 2.6.3.2.6 Adding a Message object

Synopsis: Adding a Message object to an existing Folder object. This involves creating a new Message object and adding it as a new row to the Contents TC of the parent Folder object (section [2.6.2.4.2](#)). Updating the Message object count of the parent Folder object (section [2.6.2.3.3](#)), which can have cascading effects to the parent-parent Hierarchy TC as well. Creating a Message object

involves creating a new Message object PC (section [2.6.2.3.1](#)), populating it with a minimal set of required properties (section [2.6.2.3.2](#)), and creating a Recipient TC (section [2.6.2.4.1](#)) in a subnode entry (section [2.6.1.2.2](#)).

Requirement Level	Actions
Required:	<ul style="list-style-type: none"> <li>▪ An existing Folder object (section <a href="#">2.6.3.2.1</a>).</li> <li>▪ See sections <a href="#">2.6.1.2.2</a>, <a href="#">2.6.2.3.1</a>, <a href="#">2.6.2.3.2</a>, <a href="#">2.6.2.3.3</a>, <a href="#">2.6.2.4.1</a> and <a href="#">2.6.2.4.2</a>.</li> <li>▪ See minimal set of required properties in section <a href="#">2.4.5.1.1</a>.</li> <li>▪ See minimal set of required columns for the Contents TC in <a href="#">2.4.4.5.1</a>.</li> <li>▪ See minimal set of required columns for the Recipients TC in section <a href="#">2.4.5.3.1</a>.</li> <li>▪ Parent Folder object properties MUST be updated accordingly.</li> <li>▪ MUST queue a properly-formatted SUD of type SUDT_MSG_ADD to the SMQ (section <a href="#">2.4.8.1</a>).</li> </ul>
Recommended:	None.
Optional:	None.

Possible Side Effects: See sections [2.6.3.2.1](#), [32.6.1.2.2](#), [2.6.2.3.1](#), [2.6.2.3.2](#), [2.6.2.3.3](#), [2.6.2.4.1](#) and [2.6.2.4.2](#).

### 2.6.3.2.7 Copying a Message object

Synopsis: Copying a Message object from its parent Folder object to another Folder object. To use single-instancing, this involves duplicating the Message object PC node (section [2.6.1.2.4](#)), and adding a row to the Contents TC of the new parent Folder object (section [2.6.2.4.2](#)). Some properties of the parent Folder object (for example, message count) also need to be updated (section [2.6.2.3.2](#)).

Requirement Level	Actions
Required:	<ul style="list-style-type: none"> <li>▪ An existing Message object (section <a href="#">2.6.3.2.6</a>).</li> <li>▪ An existing target Folder object (section <a href="#">2.6.3.2.1</a>).</li> <li>▪ See sections <a href="#">2.6.1.2.4</a>, <a href="#">2.6.2.3.2</a>, and <a href="#">2.6.2.4.2</a>.</li> <li>▪ See minimal set of required columns for the Contents TC in section <a href="#">2.4.4.5.1</a>.</li> <li>▪ <b>nidParent</b> of the copied Message object's NBT entry MUST be set to the NID of the target Folder object (section <a href="#">2.2.2.7.7.4</a>).</li> <li>▪ Destination Folder object properties MUST be updated accordingly.</li> <li>▪ MUST queue a properly-formatted SUD of type SUDT_MSG_ADD for the copied Message object to the SMQ (section <a href="#">2.4.8.1</a>).</li> </ul>

Requirement Level	Actions
Recommended:	None.
Optional:	None.

Possible Side Effects: See section [2.6.3.2.6](#), [2.6.3.2.1](#), [2.6.1.2.4](#), [2.6.2.3.2](#), and [2.6.2.4.2](#).

### 2.6.3.2.8 Moving a Message object

Synopsis: Moving a Message object from its parent Folder object to another Folder object. This involves deleting the Message object row from the old parent's Contents TC (section [2.6.2.4.7](#)), and adding it to the new parent's Content TC (section [2.6.2.4.2](#)). Also, some properties of both Folder object PCs (for example, message count) need to be updated (section [2.6.3.2.2](#)).

Requirement Level	Actions
Required:	<ul style="list-style-type: none"> <li>▪ An existing Message object (section <a href="#">2.6.3.2.6</a>).</li> <li>▪ An existing new parent Folder object (section <a href="#">2.6.3.2.1</a>).</li> <li>▪ See sections <a href="#">2.6.2.4.7</a>, <a href="#">2.6.2.4.2</a>, and <a href="#">2.6.3.2.2</a>.</li> <li>▪ See minimal set of required columns for the Contents TC in section <a href="#">2.4.4.5.1</a>.</li> <li>▪ <b>nidParent</b> of the moved Message object's NBT entry MUST be set to the NID of the new parent Folder object (section <a href="#">2.2.2.7.7.4</a>).</li> <li>▪ Old and new parent Folder object properties MUST be updated accordingly.</li> <li>▪ MUST queue a properly-formatted SUD of type SUDT_MSG_MOV to the SMQ (section <a href="#">2.4.8.1</a>).</li> </ul>
Recommended:	None.
Optional:	None.

Possible Side Effects: See sections [2.6.3.2.6](#), [2.6.3.2.1](#), [2.6.2.4.2](#), [2.6.2.4.7](#) and [2.6.3.2.2](#).

### 2.6.3.2.9 Deleting a sub-Folder object

Synopsis: Deleting a sub-Folder object from its parent Folder object. This involves deleting the sub-Folder object row from the Hierarchy TC of the parent Folder object (section [2.6.2.4.7](#)), updating some properties (for example, folder count) of the parent Folder object (section [2.6.3.2.2](#)), and deleting the sub-Folder object. Deleting the sub-Folder object means deleting the PC and three TCs associated with the sub-Folder object (sections [2.6.2.3.5](#) and [2.6.2.4.8](#)).

Requirement Level	Actions
Required:	<ul style="list-style-type: none"> <li>▪ An existing Folder object (section <a href="#">2.6.3.2.1</a>).</li> <li>▪ See sections <a href="#">2.6.3.2.2</a>, <a href="#">2.6.2.3.5</a>, <a href="#">2.6.2.4.8</a> and <a href="#">2.6.2.4.7</a>.</li> </ul>

Requirement Level	Actions
	<ul style="list-style-type: none"> <li>▪ Parent Folder object properties MUST be updated accordingly.</li> <li>▪ MUST queue a properly-formatted SUD of type SUDT_FLD_DEL to the SMQ (section <a href="#">2.4.8.1</a>).</li> </ul>
Recommended:	None.
Optional:	None.

Possible Side Effects: See section [2.6.3.2.1](#), [2.6.3.2.2](#), [2.6.2.3.5](#), [2.6.2.4.8](#) and [2.6.2.4.7](#).

Remarks:

- Any Folder object can be deleted by first looking up its parent, and then deleting the Folder object as a sub-Folder object of its parent. There is a ROOT Folder object in the PST that cannot be deleted; therefore, a parent Folder object MUST exist for any Folder object that can be deleted.
- If the sub-Folder object contains Message objects and/or has a sub-hierarchy, then its child Folder objects and Message objects MUST be recursively deleted before the sub-Folder object itself can be deleted.

#### 2.6.3.2.10 Deleting a Message object

Synopsis: Deleting an existing Message object from its parent Folder object. This involves deleting the Message object row from the Contents TC of the parent Folder object (section [2.6.2.4.7](#)), updating some properties (for example, message count) of the parent Folder object (section [2.6.3.2.2](#)), and deleting the Message object PC node (section [2.6.2.3.5](#)).

Requirement Level	Actions
Required:	<ul style="list-style-type: none"> <li>▪ An existing Message object (section <a href="#">2.6.3.2.6</a>).</li> <li>▪ See sections <a href="#">2.6.3.2.2</a>, <a href="#">2.6.2.3.5</a>, and <a href="#">2.6.2.4.7</a>.</li> <li>▪ Parent Folder object properties MUST be updated accordingly.</li> <li>▪ MUST queue a properly-formatted SUD of type SUDT_MSG_DEL to the SMQ (section <a href="#">2.4.8.1</a>).</li> </ul>
Recommended:	None.
Optional:	None.

Possible Side Effects: See section [2.6.3.2.6](#), [2.6.3.2.2](#), [2.6.2.3.5](#) and [2.6.2.4.7](#).

### **2.6.3.3 Message object Operations**

#### **2.6.3.3.1 Creating a Message object**

Synopsis: Creating a Message object in an existing Folder object. This is identical to section 2.6.3.2.6.

#### **2.6.3.3.2 Modifying Properties of a Message object**

Synopsis: Modifying properties of a Message object. This refers to the adding, changing and deleting of properties to/from the Message object PC, which map directly to sections [2.6.2.3.2](#), [2.6.2.3.3](#) and [2.6.2.3.4](#).

<b>Requirement Level</b>	<b>Actions</b>
Required:	<ul style="list-style-type: none"><li>▪ An existing Message object (section <a href="#">2.6.3.2.6</a>).</li><li>▪ See requirements for sections <a href="#">2.6.2.3.2</a>, <a href="#">2.6.2.3.3</a> and <a href="#">2.6.2.3.4</a>, where applicable.</li><li>▪ MUST queue a properly-formatted SUD of type SUDT_MSG_MOD to the SMQ (section <a href="#">2.4.8.1</a>).</li><li>▪ If any of the modified properties also affect the cached properties in the Contents TC of the parent Folder object, a properly-formatted SUD of type SUDT_MSG_ROW_MOD MUST also be queued.</li></ul>
Recommended:	None.
Optional:	None.

Possible Side Effects: See sections [2.6.3.2.6](#), [2.6.2.3.2](#), [2.6.2.3.3](#) and [2.6.2.3.4](#), where applicable.

Remarks:

- Some Message object properties are also duplicated in the Contents TC of the parent Folder object (section [2.4.4.5.1](#)). Implementations MUST pay special attention to any properties that are duplicated elsewhere to make sure all instances of the properties are properly updated.
- Certain Special calculated properties exist that do not map directly to externally-published properties and therefore MUST be converted, calculated or otherwise translated before persisting to or retrieving from the PST. A list of such special properties is found in section [2.5](#).

#### **2.6.3.3.3 Adding a Recipient**

Synopsis: Adding a Recipient to an existing Message object. This involves adding a row to the Recipient TC of the Message object (section [2.6.2.4.2](#)), and updating some properties (for example, recipient count) in the Message object PC (section [2.6.3.3.2](#)).

<b>Requirement Level</b>	<b>Actions</b>
Required:	<ul style="list-style-type: none"><li>▪ An existing Message object (section <a href="#">2.6.3.2.6</a>).</li></ul>

Requirement Level	Actions
	<ul style="list-style-type: none"> <li>▪ See sections <a href="#">2.6.3.3.2</a> and <a href="#">2.6.2.4.2</a>.</li> <li>▪ See minimal set of required columns for the Recipients TC in section <a href="#">2.4.5.3.1</a>.</li> <li>▪ The Message object properties MUST be updated as appropriate.</li> <li>▪ MUST queue a properly-formatted SUD of type SUDT_MSG_MOD to the SMQ (section <a href="#">2.4.8.1</a>).</li> </ul>
Recommended:	None.
Optional:	None.

Possible Side Effects: See sections [2.6.3.2.6](#), [2.6.3.3.2](#) and [2.6.2.4.2](#).

#### 2.6.3.3.4 Modifying Recipient Properties

Synopsis: Modifying the properties of an existing Recipient. This is identical to modifying Content of a Table Row (section [2.6.2.4.3](#)) or Deleting the value of a Column (section [2.6.2.4.5](#)).

Requirement Level	Actions
Required:	<ul style="list-style-type: none"> <li>▪ An existing Message object (section <a href="#">2.6.3.2.6</a>).</li> <li>▪ See section <a href="#">2.6.2.4.3</a> and <a href="#">2.6.2.4.5</a>.</li> <li>▪ MUST queue a properly-formatted SUD of type SUDT_MSG_MOD to the SMQ (section <a href="#">2.4.8.1</a>).</li> </ul>
Recommended:	None.
Optional:	None.

Possible Side Effects: See sections [2.6.3.2.6](#), [2.6.2.4.3](#) and [2.6.2.4.5](#).

#### 2.6.3.3.5 Adding an Attachment object

Synopsis: Adding an Attachment object to a Message object. This involves creating an Attachments TC in a subnode entry if it does not already exist (sections [2.6.1.2.2](#) and [2.6.2.4.1](#)), creating an Attachment object PC (section [2.6.2.3.1](#)) and adding it as a new row to the Attachments TC (section [2.6.2.4.2](#)), and updating some properties (for example, attachment count) in the Message object PC (section [2.6.3.3.2](#)).

Requirement Level	Actions
Required:	<ul style="list-style-type: none"> <li>▪ An existing Message object (section <a href="#">2.6.3.2.6</a>).</li> <li>▪ See sections <a href="#">2.6.1.2.2</a>, <a href="#">2.6.2.3.1</a>, <a href="#">2.6.3.3.2</a>, <a href="#">2.6.2.4.1</a> and <a href="#">2.6.2.4.2</a>.</li> <li>▪ See minimal set of required columns for the Attachments TC in section</li> </ul>

Requirement Level	Actions
	<p><a href="#">2.4.6.1.1</a>.</p> <ul style="list-style-type: none"> <li>▪ See minimal set of required properties for the Attachment object PC in section <a href="#">2.4.6.2.1</a>.</li> <li>▪ The Message object properties MUST be updated as appropriate.</li> <li>▪ MUST queue a properly-formatted SUD of type SUDT_MSG_MOD to the SMQ (section <a href="#">2.4.8.1</a>).</li> </ul>
Recommended:	None.
Optional:	None.

Possible Side Effects: See sections [2.6.3.2.6](#), [2.6.1.2.2](#), [2.6.2.3.1](#), [2.6.3.3.2](#), [2.6.2.4.1](#) and [2.6.2.4.2](#).

Remarks:

- Attachment objects are optional and the Attachments TC is not created until the first Attachment object is added to a Message object.

### 2.6.3.3.6 Modifying Properties of an Attachment object

Synopsis: Modifying properties of an Attachment object. This refers to the adding, changing and deleting of properties to/from the Attachment object PC, which map directly to sections [2.6.2.3.2](#), [2.6.2.3.3](#), and [2.6.2.3.4](#).

Requirement Level	Actions
Required:	<ul style="list-style-type: none"> <li>▪ An existing Attachment object (section <a href="#">2.6.3.3.5</a>).</li> <li>▪ See sections <a href="#">2.6.2.3.2</a>, <a href="#">2.6.2.3.3</a>, and <a href="#">2.6.2.3.4</a>, where applicable.</li> <li>▪ MUST queue a properly-formatted SUD of type SUDT_MSG_MOD to the SMQ (section <a href="#">2.4.8.1</a>).</li> </ul>
Recommended:	None.
Optional:	None.

Possible Side Effects: See sections [2.6.3.3.5](#), [2.6.2.3.2](#), [2.6.2.3.3](#), and [2.6.2.3.4](#), where applicable.

Remarks:

- Some Attachment object properties are also duplicated in the Attachments TC (section [2.4.6.1.1](#)). Implementations MUST pay special attention to any properties that are duplicated elsewhere to make sure all instances of the properties are properly updated.

### **2.6.3.3.7 Deleting a Recipient**

Synopsis: Deleting an existing Recipient from a Message object. This involves deleting the corresponding row in the Recipients TC (section [2.6.2.4.7](#)) and updating some properties (for example, recipient count) in the Message object PC (section [2.6.3.3.2](#)).

Requirement Level	Actions
Required:	<ul style="list-style-type: none"><li>▪ An existing Recipient (section <a href="#">2.6.3.3.3</a>).</li><li>▪ See sections <a href="#">2.6.2.4.7</a> and <a href="#">2.6.3.3.2</a>.</li><li>▪ The Message object properties MUST be updated as appropriate.</li><li>▪ MUST queue a properly-formatted SUD of type SUDT_MSG_MOD to the SMQ (section <a href="#">2.4.8.1</a>).</li></ul>
Recommended:	None.
Optional:	None.

Possible Side Effects: See sections [2.6.3.3.3](#), [2.6.3.3.2](#) and [2.6.2.4.7](#).

### **2.6.3.3.8 Deleting an Attachment object**

Synopsis: Deleting an existing Attachment object from a Message object. This involves deleting the Attachment object PC (section [2.6.2.3.5](#)) and its corresponding row in the Attachments TC (section [2.6.2.4.7](#)) and updating some properties (for example, attachment count) in the Message object PC (section [2.6.3.3.2](#)).

Requirement Level	Actions
Required:	<ul style="list-style-type: none"><li>▪ An existing Attachment object (section <a href="#">2.6.3.3.5</a>).</li><li>▪ See sections <a href="#">2.6.3.3.2</a> and <a href="#">2.6.2.4.7</a>.</li><li>▪ The Message object properties MUST be updated as appropriate.</li><li>▪ MUST queue a properly-formatted SUD of type SUDT_MSG_MOD to the SMQ (section <a href="#">2.4.8.1</a>).</li></ul>
Recommended:	None.
Optional:	None.

Possible Side Effects: See sections [2.6.3.3.5](#), [2.6.3.3.2](#) and [2.6.2.4.7](#).

## **2.6.3.4 Name-to-ID Map Operations**

### **2.6.3.4.1 Creating the Name-to-ID Map**

Synopsis: Creating the Name-to-ID Map. This involves creating a PC with a special NID (section 2.6.2.3.1), with one special property (section 2.6.2.3.2).

Requirement Level	Actions
Required:	<ul style="list-style-type: none"> <li>▪ See sections 2.6.2.3.1 and 2.6.2.3.2.</li> <li>▪ <b>PidTagNameidBucketCount</b> MUST be added to the PC with a value of 251 (0xFB)</li> </ul>
Recommended:	None
Optional:	None

Possible Side Effects: See sections 2.6.2.3.1 and 2.6.2.3.2.

Remarks:

- The Name-to-ID Map MUST exist.

#### 2.6.3.4.2 Adding a Named Property

Synopsis: Adding a named property to the Name-to-ID Map. This involves adding or modifying the **PidTagNameidStreamEntry** property, adding or modifying the **PidTagNameidStreamString** or **PidTagNameidStreamGuid** properties depending on named property type, and finally adding or modifying the corresponding hash bucket properties (sections [2.6.2.3.2](#), [2.6.2.3.3](#)).

Requirement Level	Actions
Required:	<ul style="list-style-type: none"> <li>▪ An existing Name-to-ID Map (section <a href="#">2.6.3.4.1</a>).</li> <li>▪ See sections <a href="#">2.6.2.3.2</a> and <a href="#">2.6.2.3.3</a>.</li> </ul>
Recommended:	None.
Optional:	None.

Possible Side Effects: See sections [2.6.3.4.1](#), [2.6.2.3.2](#) and [2.6.2.3.3](#).

#### 2.6.3.4.3 Deleting a Named Property

Synopsis: Deleting a named property from the Name-to-ID Map.

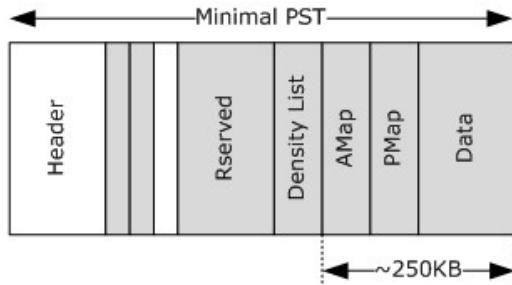

Remarks:

- Implementations SHOULD NOT remove named properties from the Name-to-ID Map.

### 2.7 Minimum PST Requirements

This section covers the specific requirement for a PST. While the previous sections have provided detailed technical requirements of how to create and maintain a structurally-correct PST file, the following sections cover the additional requirements on the actual contents of the PST.

The essential elements of a minimal working PST file are visually represented in the following diagram.

**Figure 19: Minimal PST**

### 2.7.1 Mandatory Nodes

The following table lists the absolute minimum list of nodes that MUST be present in a PST. Implementations SHOULD consider the PST invalid if any of the nodes are missing or are incorrectly formed. The NIDs in bold are fixed NID values, where the others are sample NIDs that can be any valid NID value for its respective NID\_TYPE.

NID	NID_TYPE	Special NID (if applicable)	Object	Minimal State
0x0021	NID_TYPE_INTERNAL	NID_MESSAGE_STORE	PC	Schem a Props
0x0061	NID_TYPE_INTERNAL	NID_NAME_TO_ID_MAP	PC	Empty
0x0122	NID_TYPE_NORMAL_FOLDER	NID_ROOT_FOLDER	PC	Schem a Props
0x012D	NID_TYPE_HIERARCHY_TABLE	<Root Folder object>	TC	2 Rows
0x012E	NID_TYPE_CONTENTS_TABLE	<Root Folder object>	TC	Column s Only
0x012F	NID_TYPE_ASSOC_CONTENTS_TABLE	<Root Folder object>	TC	Column s Only
0x01E1	NID_TYPE_INTERNAL	NID_SEARCH_MANAGEMENT_QUEUE	node	
0x0201	NID_TYPE_INTERNAL	NID_SEARCH_ACTIVITY_LIST	node	Empty
0x060D	NID_TYPE_HIERRCHY_TABLE	NID_HIERARCHY_TABLE_TEMPLATE	TC	Column s Only
0x060E	NID_TYPE_CONTENTS_TABLE	NID_CONTENTS_TABLE_TEMPLATE	TC	Column s Only
0x060F	NID_TYPE_ASSOC_CONTENTS_TABLE	NID_ASSOC_CONTENTS_TABLE_TEMPLATE	TC	Column s Only
0x061	NID_TYPE_SEARCH_CONTENTS_TABLE	NID_SEARCH_CONTENTS_TABLE_TEMP	TC	Column

<b>NID</b>	<b>NID_TYPE</b>	<b>Special NID (if applicable)</b>	<b>Object</b>	<b>Minimal State</b>
0	BLE	LATE		s Only
0x0692	NID_TYPE_RECIPIENT_TABLE	NID_RECIPIENT_TABLE	TC	Column s Only
0x0671	NID_TYPE_ATTACHMENT_TABLE	NID_ATTACHMENT_TABLE	TC	Column s Only
0x2223	NID_TYPE_SEARCH_FOLDER	<Spam search Folder object>	PC	Column s Only
0x8022	NID_TYPE_NORMAL_FOLDER	<IPM SuBTree>	PC	Schem a Props
0x802D	NID_TYPE_HIERARCHY_TABLE	<IPM SuBTree>	TC	2 Rows
0x802E	NID_TYPE_CONTENTS_TABLE	<IPM SuBTree>	TC	Column s Only
0x802F	NID_TYPE_ASSOC_CONTENTS_TABLE	<IPM SuBTree>	TC	Column s Only
0x8042	NID_TYPE_NORMAL_FOLDER	<Search Folder objects>	PC	Schem a Props
0x804D	NID_TYPE_HIERARCHY_TABLE	<Search Folder objects>	TC	Column s Only
0x804E	NID_TYPE_CONTENTS_TABLE	<Search Folder objects>	TC	Column s Only
0x804F	NID_TYPE_ASSOC_CONTENTS_TABLE	<Search Folder objects>	TC	Column s Only
0x8062	NID_TYPE_NORMAL_FOLDER	<Deleted Items>	PC	Schem a Props
0x806D	NID_TYPE_HIERARCHY_TABLE	<Deleted Items>	TC	Column s Only
0x806E	NID_TYPE_CONTENTS_TABLE	<Deleted Items>	TC	Column s Only
0x806F	NID_TYPE_ASSOC_CONTENTS_TABLE	<Deleted Items>	TC	Column s Only

## 2.7.2 Minimum Folder Hierarchy

The following is the minimum folder hierarchy required for a PST:

- Root Folder (section 2.7.3.4.1)
  - Top of Personal Folders (IPM SuBTree) (section 2.7.3.4.2)
    - Deleted Items (section 2.7.3.4.5)

- Search Root (section 2.7.3.4.3)
- Spam search Folder (section 2.7.3.4.4)

### 2.7.3 Minimum Object Requirements

This section presents the minimum requirements for a PST, which include the mandatory nodes as well as the minimum set of properties that is required for each type of PST Object.

#### 2.7.3.1 Message store

See section 2.4.3.1 for the minimum requirements of the Message store.

#### 2.7.3.2 Name-to-ID Map

The minimum requirement for the Name-to-ID Map is a PC node with a single property **PidTagNameIdBucketCount** set to a value of 251 (0xFB). Refer to section 2.4.7 for details.

#### 2.7.3.3 Template Objects

The following template Objects MUST be present in the PST. Each template object is a TC with a pre-defined set of columns, but no data rows.

- NID\_HIERARCHY\_TABLE\_TEMPLATE – see section 2.4.4.4.1 for column list.
- NID\_CONTENTS\_TABLE\_TEMPLATE – see section 2.4.4.5.1 for column list.
- NID\_ASSOC\_CONTENTS\_TABLE\_TEMPLATE – see section 2.4.4.6.1 for column list.
- NID\_SEARCH\_CONTENTS\_TABLE\_TEMPLATE – see section 2.4.8.6.2.1 for column list.
- NID\_RECIPIENT\_TABLE – see section 2.4.5.3.1 for column list.
- NID\_ATTACHMENT\_TABLE – see section 2.4.6.1.1 for column list.

#### 2.7.3.4 Folders

##### 2.7.3.4.1 Root Folder

- Folder object PC – **nidParent** = self; Schema properties initialized as follows.

Property Identifier	Property Type	Friendly Name	Value
0x3001	<b>PtypString</b>	<b>PidTagDisplayNameW</b>	""
0x3602	<b>PtypInteger32</b>	<b>PidTagContentCount</b>	3
0x3603	<b>PtypInteger32</b>	<b>PidTagContentUnreadCount</b>	0
0x360A	<b>PtypBoolean</b>	<b>PidTagSubfolders</b>	1 (TRUE)

- Hierarchy TC – Columns from section [2.4.4.4.1](#); 3 rows: "IPM SuBTree", "Search Root" and "Spam Search Folder"
- Contents TC – Columns from section [2.4.4.5.1](#); no rows.

- FAI contents table TC: Columns from section [2.4.4.6.1](#); no rows.

#### 2.7.3.4.2 Top of Personal Folders (IPM SuBTree)

- Folder object PC – **nidParent** = Root Folder; Schema properties initialized as follows.

Property Identifier	Property Type	Friendly Name	Value
0x3001	PtypString	PidTagDisplayNameW	"Top of Personal Folders"
0x3602	PtypInteger32	PidTagContentCount	1
0x3603	PtypInteger32	PidTagContentUnreadCount	0
0x360A	PtypBoolean	PidTagSubfolders	1 (TRUE)

- Hierarchy TC – Columns from section [2.4.4.4.1](#); 1 row: "Deleted Items"
- Contents TC – Columns from section [2.4.4.5.1](#); no rows.
- FAI contents table TC: Columns from section [2.4.4.6.1](#); no rows.

#### 2.7.3.4.3 Search Root

- Folder object PC – **nidParent** = Root Folder; Schema properties initialized as follows.

Property Identifier	Property Type	Friendly Name	Value
0x3001	PtypString	PidTagDisplayNameW	"Search Root"
0x3602	PtypInteger32	PidTagContentCount	0
0x3603	PtypInteger32	PidTagContentUnreadCount	0
0x360A	PtypBoolean	PidTagSubfolders	0 (FALSE)

- Hierarchy TC – Columns from section [2.4.4.4.1](#); no rows.
- Contents TC – Columns from section [2.4.4.5.1](#); no rows.
- FAI contents table TC: Columns from section [2.4.4.6.1](#); no rows.

#### 2.7.3.4.4 Spam Search Folder

- Folder object PC – **nidParent** = Root Folder; Schema properties initialized as follows.

Property Identifier	Property Type	Friendly Name	Value
0x3001	PtypString	PidTagDisplayNameW	"SPAM Search Folder 2"
0x3602	PtypInteger32	PidTagContentCount	0
0x3603	PtypInteger32	PidTagContentUnreadCount	0
0x360A	PtypBoolean	PidTagSubfolders	0 (FALSE)

- Hierarchy TC – Columns from section [2.4.4.4.1](#); no rows.

- Contents TC – Columns from section [2.4.4.5.1](#); no rows.
- FAI contents table TC: Columns from section [2.4.4.6.1](#); no rows.

#### 2.7.3.4.5 Deleted Items

- Folder object PC – **nidParent** = IPM SuBTree; Schema properties initialized as follows:

Property Identifier	Property Type	Friendly Name	Value
0x3001	PtypString	PidTagDisplayNameW	"Deleted Items"
0x3602	PtypInteger32	PidTagContentCount	0
0x3603	PtypInteger32	PidTagContentUnreadCount	0
0x360A	PtypBoolean	PidTagSubfolders	0 (FALSE)

- Hierarchy TC – Columns from section [2.4.4.4.1](#); no rows.
- Contents TC – Columns from section [2.4.4.5.1](#); no rows.
- FAI contents table TC: Columns from section [2.4.4.6.1](#); no rows.

#### 2.7.3.5 Search-related Objects

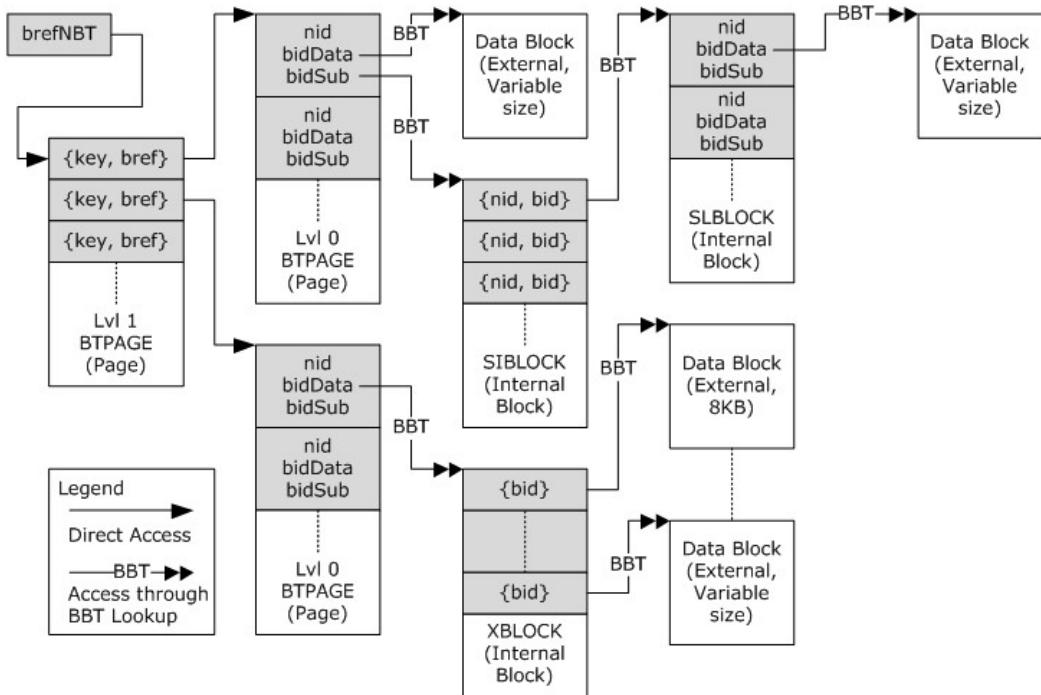

Search Management Queue – see section [2.4.8.4.1](#) for details. An empty queue node MUST be created for the minimal PST.

Search Activity List – see section [2.4.8.4.2](#) for details. An empty SAL node MUST be created for the minimal PST.

### 3 Structure Examples

#### 3.1 Sample Node Database (NDB)

The following is a sample illustration of how various pages and blocks are used to represent various entities of the NDB Layer.

**Figure 20: Application of Pages and Blocks**

The first and second columns of the diagram represent the NBT, which is accessed through the **BREFNBT** structure in the ROOT structure. In this example, the NBT consists of a 2-level BTree that contains a number of top-level nodes. In the second column, the node on the top contains both a data BID (**bidData**) and a subnode BID (**bidSub**), whereas the node on the bottom only contains a data BID but no subnode.

Notice in the Legend that there are two types of arrow notations. The single arrowhead indicates data that can be directly accessed by means of a **BREF** structure (which contains the absolute file offset of the target); and the double-arrowhead with "BBT" indicates data that needs to be accessed indirectly using a BBT search to lookup the data block that is associated with the BID.

The top node's **bidData** points directly to a data block, which contains the external, end-user data associated with this node.

In addition, the top node also contains a subnode, which points to a 2-level subnode BTree. The Level 1 SIBLOCK fans out to a number of different Level 0 SLBLOCKs (only one is shown in the diagram for simplicity). Each SLBLOCK further contains a number of internal subnodes (4<sup>th</sup> column). In this example, the internal subnode points to a single data block (5<sup>th</sup> column). The subnode can recursively contain any number of levels of subnodes to create a hierarchical tree of subnodes.

The second top-level node (bottom node in 2<sup>nd</sup> column) is an example of a data tree with one XBLOCK, which contains an array of BIDs that point to several data blocks that contains the end-user data.

### 3.2 Sample HEADER

The following is a sample binary dump of a Unicode PST File header (section [2.2.2.6](#)), followed by the corresponding annotated, parsed contents.

```

00000000000000000000 21 42 44 4E 0E A9 9A 37-53 4D 17 00 13 00 01 01 *!BDN...7SM.....*

### 3.3 Sample Intermediate BT Page

The following is a binary dump of a sample intermediate BT page (both intermediate NBT and BBT pages share this format). The page itself is 512 bytes in size, including the PAGETRAILER structure (section [2.2.2.7.1](#)), which is indicated by 16 bytes at the end of the page. The page contains BTENTRY structures (section [2.2.2.7.7.1](#)), which start from the very beginning of the page, and the 4 bytes before the PAGETRAILER are the 4 byte values of the BTPAGE structure (section [2.2.2.7.7.1](#)).

In this particular example, this is an intermediate BT page (**cLevel**=1), with 3 BTENTRY items (**cEnt**=3), each of size 0x18 bytes (**cbEnt**=0x18), and the maximum capacity of the page is 0x14 BTENTRY structures (**cEntMax**=0x14). Note the unused space in this example is zero-filled. However, in practice, the unused space can contain any value, as long as the CRC in the PAGETRAILER match its contents.

000000000000083F0 81 81 06 80 64 B1 E8 02-06 02 00 00 00 00 00 00 *....d.....*
```

The following 16 bytes of the preceding binary dump of a sample intermediate BT page indicate the PAGETRAILER structure (section [2.2.2.7.1](#)).

```
000000000000083F0 81 81 06 80 64 B1 E8 02-06 02 00 00 00 00 00 00 *....d.....*
```

The 4 bytes (03 14 18 01) of the preceding binary dump of a sample intermediate BT page indicate the BTPAGE structure (section [2.2.2.7.7.1](#)).

```
000000000000083E0 00 00 00 00 00 00 00-03 14 18 01 00 00 00 00 *.....*
```

### 3.4 Sample Leaf NBT Page

The following is a binary dump of a sample leaf NBT entry (section [2.2.2.7.7.4](#)). The page itself is 512 bytes in size, including the PAGETRAILER structure (section [2.2.2.7.1](#)), which is indicated by the 16 bytes at the end of the page. The NBTENTRY structures start from the very beginning of the page, and the 4 bytes before the PAGETRAILER are the 4 byte values of the BTPAGE structure (section [2.2.2.7.7.1](#)).

In this particular example, this is a leaf NBT page (**cLevel**=0), with 0x0E NBENTRY items (**cEnt**=0x0E), each of size 0x20 bytes (**cbEnt**=0x20), and the maximum capacity of the page is 0x0F NBENTRY structures (**cEntMax**=0x0F).

Note that the actual size of the NBENTRY is only 0x1C bytes, but the **cbEnt** field in the BTPAGE is 0x20 instead. Implementations will always use the length specified in the **cbEnt** field, regardless of the native size of the actual data records. Also note that the unused bytes can contain any value as long as the CRC in the PAGETRAILER match its contents.

```
00000000000007000 0F 06 00 00 00 00 00-0C 00 00 00 00 00 00 00 00 *.....*
00000000000007010 00 00 00 00 00 00 00-00 00 00 00 02 00 00 00 00 *.....*

### 3.5 Sample Leaf BBT Page

The following is a binary dump of a sample leaf BBT entry (section [2.2.2.7.7.3](#)). The page itself is 512 bytes in size, including the PAGETRAILER structure (section [2.2.2.7.1](#)), which is indicated by 16 bytes at the end of the page. The BBTENTRY structures start from the very beginning of the page, and the 4 bytes before the PAGETRAILER are the 4 byte values of the BTPAGE structure (section [2.2.2.7.7.1](#)).

In this particular example, this is a leaf BBT page (**cLevel**=0), with 8 NBENTRY items (**cEnt**=8), each of size 0x18 bytes (**cbEnt**=0x18), and the maximum capacity of the page is 0x14 NBTENTRY structures (**cEntMax**=0x14). Note the unused space in this example is zero-filled. However, in practice, the unused space can contain any value, as long as the CRC in the PAGETRAILER match its contents.

```

## 3.6 Sample Data Tree

The following is a binary dump of a data tree (section [2.2.2.8.3.2](#)), which is identified by a data block (that is, **bidData**) that has the **i** bit set. In this example, the data tree consists of a single XBLOCK. The first 8 bytes of the XBLOCK (01 01 35 00 49 9C 06 00) contain metadata about the XBLOCK, and the rest of the data contains an array of BIDs that refer to the data blocks that contain the actual end-user data.

The size of an XBLOCK varies anywhere from 64 to 8192 bytes, including the BLOCKTRAILER structure (section [2.2.2.8.1](#)). The last 16 bytes at the end of this example (B0 01 38 67 51 CD EE 3F-62 01 00 00 00 00 00 00) represent the BLOCKTRAILER.

In this specific example, the XBLOCK contains 0x35 BIDs (**cEnt**=0x35), which contains 0x69C49 bytes of actual data (**lcbTotal**=0x00069C49).

```

### 3.7 Sample SLBLOCK

The following is a binary dump of a SLBLOCK structure (section [2.2.2.8.3.3.1.1](#)), which is used to represent a subnode. The first 8 (02 00 01 00 00 00 00 00) bytes contain the metadata about the SLBLOCK, which are followed by an SLENTRY structure (section [2.2.2.8.3.3.1.1](#)). SIBLOCK structures, which are not shown in this example, have the same general format, but contain SIENTRY structures (section [2.2.2.8.3.3.2.1](#)) instead.

The size of an SLBLOCK varies anywhere from 64 to 8192 bytes, including the BLOCKTRAILER structure (section [2.2.2.8.1](#)). The last 16 bytes at the end of this example (20 00 5F 5E 50 5E D4 D9-86 13 00 00 00 00 00 00) represent the BLOCKTRAILER.

In this particular example, this is an SLBLOCK (**cLevel**=0) with only 1 SLENTRY (**cEnt**=1). This example also illustrates the smallest possible SLBLOCK (64 bytes).

```

00000000000594D80 02 00 01 00 00 00 00-7F 81 00 00 00 00 00 00 00 *.....*

```

### 3.8 Sample Heap-on-Node (HN)

The following is the binary dump of an HN (section [2.3.1](#)). The first 12 bytes (EC 00 EC BC 20 00 00 00-00 00 00 00) indicate the HNHDR structure (section [2.3.1.2](#)), which contain information about the HN. The last 22 bytes (shown following) represent the HNPAGEMAP structure (section [2.3.1.5](#)), which contains the information about each allocated heap block.

```

08 00 00 00 *.....}.pb.....*  

000000000000048F0 0C 00 14 00 6C 00 7C 00-8C 00 A4 00 BC 00 D4 00 *....l.|.....*  

00000000000004900 EC 00 *..*

```

In this particular example, the signature indicates a HN (**bSig**=0xEC) which ultimately contains a PC (**bClientSig**=0xBC (**bTypePC**)). The metadata of the next-level client is stored in HID 0x20 (**hidUserRoot**=0x00000020). The HNPAGEMAP structure can be found at offset 0xEC with respect to the beginning of the HN (**ibHnPM**=0x00EC).

The HNPAGEMAP indicate that the HN has 8 allocations (**cAlloc**=8), and the starting offsets of the allocations (with respect to the beginning of the HN) are: 0x0C, 0x14, 0x6C, 0x7C, 0x8C, 0xA4, 0xBC, 0xD4, respectively. And finally, the next allocation starts at offset 0xEC.

00000000000004900 EC 00 *..*

```

### 3.9 Sample BTH

Because the binary dump in the preceding example contains a PC, by definition it follows that the HN contains a BTH. This example uses the same binary dump form the last example to further examine the inner BTH structure (section [2.3.2](#)). Because **hidUserRoot** is 0x20, this maps to the first HN allocation (section [2.3.1.1](#)), which starts at offset 0x0C. Because the next allocation starts at offset 0x14, its size is 8 bytes.

These 8 bytes (B5 02 06 00 40 00 00 00) actually maps to the BTHHEADER structure (section [2.3.2.1](#)) of this BTH. According to the information in the BTHHEADER, each record in this BTH has a 2-byte key (**cbKey**=2) and 6 bytes of data (**cbEnt**=6). It also indicates that the BTH entry table is located in HID 0x40 (hidRoot=0x00000040), and it contains leaf BTH Records (**bIdxLevels**=0, see section [2.3.2.3](#)).

HID 0x40 maps to the second allocation, which spans 0x58 bytes from offset 0x14 to 0x6C (shown following). Because each record is 8 bytes (2+6), the BTH contains 11 records.

```

34 0E 02 01-A0 00 00 00 38 0E 03 00 *@....4.....8...*  

00000000000004820 00 00 00 00 F9 0F 02 01-60 00 00 00 01 30 1F 00 *.....`.....0..*  

00000000000004830 80 00 00 00 DF 35 03 00-89 00 00 00 E0 35 02 01 *....5.....5..*  

00000000000004840 C0 00 00 00 E3 35 02 01-00 01 00 00 E7 35 02 01 *....5.....5..*  

00000000000004850 E0 00 00 00 33 66 0B 00-01 00 00 00 FA 66 03 00 *....3f.....f..*  

00000000000004860 OD 00 0E 00 FF 67 03 00-00 00 00 00 22 9D B5 0A *....g....."...

```

Recall that the HN has 8 allocations, but so far the BTH only used accounted for 2 of them. The remaining 6 allocations are being used by the higher-level client (that is, the PC).

```

00000000000004800 EC 00 EC BC 20 00 00 00-00 00 00 00 B5 02 06 00 *.... .....*

### 3.10 Sample Message store

The binary data used in the last 2 examples (HN, BTH) is actually that of the Message store PC of a PST. The following is the decoded content of the PC in the preceding example, which contains all the properties of the Message store.

```

NID: 33 (0x00000021) < NID_TYPE_INTERNAL > < NID_MESSAGE_STORE >

Parent NID: 0x00000000
Data BID: 168 (0xa8)
Subnode BID: 0 (0x0)

Block: IB=18432 (0x4800), 258 (0x102) bytes
Block Signature: 0xec < HEAP_SIGNATURE >
Client Signature: 0xbc < bTypePC >
Fill Level: 0x00 0x00 0x00 0x00
User Root HID: 32 (0x00000020)

### 3.11 Sample TC

The following is a binary dump of a TC (section [2.3.4](#)), which is small enough to be self-contained in a data block (that is, not subnode) to keep things simple. Because of the complexity of the TC, a number of decorations are used to represent the different constructs in the binary data.

A TC is constructed on top of an HN structure, which is shown following by the 32 bytes from the beginning and end of the data.

```
00000000000004A00 BC 01 EC 7C 40 00 00 00-00 00 00 00  
...  
...  
00000000000004BC0 OC 00 14 00 92 00 AA 00-4F 01 7D 01 93 01 BB 01 *.....O}....*
```

The **hidUserRoot** of the HN points to the TCINFO structure (section [2.3.4.1](#)), which is at HID 0x40 and indicated by the underlined bytes. In this example, the TC contains 0x0D columns (**cCols**=0x0D), and contains an embedded BTH (RowIndex, section [2.3.4.3](#)) at HID 0x20. The Row Matrix (actual row data, section [2.3.4.4](#)) is found at HID 0x80. The items that are shown following represent the **TCOLDESC** structures that describe each of the columns in the TC (section [2.3.4.2](#)).

```
02 01 30 0E 14 00 *.....0...*  
00000000000004A30 04 06 14 00 33 0E 18 00-08 07 02 01 34 0E 20 00 *...3.....4. .*  
00000000000004A40 04 08 03 00 38 0E 24 00-04 09 1F 00 01 30 08 00 *...8.$.....0.*  
00000000000004A50 04 02 03 00 02 36 0C 00-04 03 03 00 03 36 10 00 *...6.....6..*  
00000000000004A60 04 04 0B 00 0A 36 34 00-01 05 1F 00 13 36 28 00 *...64.....6(.  
00000000000004A70 04 0A 03 00 35 66 2C 00-04 0B 03 00 36 66 30 00 *...5f,...6f0.*  
00000000000004A80 04 0C 03 00 F2 67 00 00-04 00 03 00 F3 67 04 00 *...g.....g.*  
00000000000004A90 04 01
```

The two following pieces of data collectively make up the RowIndex, which associate each row in the TC with the corresponding NID of the item it refers to.

```
B5 04 04 00  
*...|@.....*  
00000000000004A10 60 00 00 00  
...  
...  
23 22 00 00 02 00-00 00 22 80 00 00 00 00  
*..#". ...."....*  
0000000000004AA0 00 00 42 80 00 00 01 00-00 00
```

Finally, the following data constitutes the Row Matrix. The remaining, undecorated data near the end are additional allocations off the HN to store variable-size property data in the Row Matrix.

```
22 80 00 00 0E 00 *.B....."....*  
00000000000004AB0 00 00 A0 00 00 00 00 00-00 00 00 00 00 00 00 00 00  
00000000000004AC0 00 00 00 00 00 00 00 00-00 00 00 00 00 00 00 00 00

### 3.12 Sample Folder object

The following is a full content dump of the Root Folder. Note the 4 constituents that collectively make up a Folder object. The Hierarchy TC indicates that the Root Folder has 3 sub-Folder objects: "Top of Personal Folders", "Search Root" and "SPAM Search Folder 2". The Contents TC and FAI contents table TC indicate that the Root Folder has no Message objects or FAI Message objects. Also note that the parent NID of the Root Folder points to itself.

```

### 3.13 Sample Message object

The following is the parsed content of a sample Message object that is sent from an imaginary user account to itself. The intention of this is to provide a SAMPLE of what types of properties can be found in a typical Message object and is by no means a definitive reference. Note the presence of a Recipient TC in addition to the Message object PC.

## 4 Security Considerations

### 4.1 Strength of encoded PST data blocks

This protocol uses two keyless cipher algorithms to encode the data blocks in the PST. These algorithms only provide data obfuscation and can be conveniently decoded once the exact encoding algorithm is understood.

Moreover, only end-user data blocks are encoded in the PST. All the other infrastructure information, including the header, allocation metadata pages and BTree pages are stored without obfuscation.

In summary, the strength of the encoded PST data blocks provides no additional security beyond data obfuscation.

### 4.2 Strength of PST Password

The PST Password, which is stored as a property value in the Message store, is a superficial mechanism that requires the client implementation to enforce the stored password. Because the password itself is not used as a key to the encoding and decoding cipher algorithms, it does not provide any security benefit to preventing the PST data to be read by unauthorized parties.

Moreover, the password is stored as a CRC-32 hash of the original password string, which is prone to collisions and is relatively weak against a brute-force approach.

## 5 Appendix A: PST Data Algorithms

This section contains source code listings for the various algorithms that have been referenced in this document. While every effort has been made to ensure the correctness of the source code, please note that the source code is presented here as a reference, and is not intended for direct adoption for production use. All source code in the following sections is in C++.

### 5.1 Permutative Encoding

The following algorithm is used for NDB\_CRYPT\_PERMUTE. While pv and cb represent the buffer and size for the data to encode/decode, the value for fEncrypt specifies whether the input data is encoded (TRUE) or decoded (FALSE). Note that the data is encoded / decoded in-place.

```

        *pb = pbTable[*pb];
}

```

## 5.2 Cyclic Encoding

The following algorithm is used for NDB\_CRYPT\_CYCLIC. Note that this is a symmetric cipher that is used to both encode and decode. While **pv** and **cb** represent the buffer and size for the data to

encode/decode, the value to use for **dwKey** is the lower DWORD of the BID associated with this data block. Note that the data is encoded / decoded in-place.

```
void CryptCyclic(PVOID pv, int cb, DWORD dwKey)
{
    byte * pb = (byte *)pv;
    byte b;
    WORD w;

    w = (WORD) (dwKey ^ (dwKey >> 16));

    while (--cb >= 0) {
        b = *pb;
        b = (byte) (b + (byte)w);
        b = mpbbR[b];
        b = (byte) (b + (byte) (w >> 8));
        b = mpbbS[b];
        b = (byte) (b - (byte) (w >> 8));
        b = mpbbI[b];
        b = (byte) (b - (byte)w);
        *pb++ = b;

        w = (WORD) (w + 1);
    }
}
```

### 5.3 CRC Calculation

The following is the algorithm used to calculate the all the CRCs mentioned in this document. dwCRC is an optional seed value to be used to initialize the CRC calculation, which MUST be zero (0) in the context of this document. The arguments pv and cbLength represent the data for which the CRC is to be calculated. This function returns the calculated CRC of the input arguments.

```

    }
}

```

## 5.4 Conversation ID

The following is the algorithm used to calculate the Conversation ID (PidTagConversationId) for a given Message object based on the values of the PidTagConversationIndex (PtypBinary), PidTagConversationTopic (PtypString), and PidTagConversationTracking (PtypBoolean) properties in the Message object. This algorithm is referenced in sections [2.5.3.1](#) and [2.5.3.1.1](#), and the main entry point is HrComputeConvID.

The arguments for HrComputeConvID are as follows: pbConvIndex and cbConvIndex represents the binary value of the PidTagConversationIndex property (NULL if the property is not present); pwzConvTopic is the Unicode string value of the PidTagConversationTopic property (NULL if property not present); and fConvTracking is the BOOLEAN value of the PidTagConversationTracking property (default is FALSE if property not present). On SUCCESS, guidConvID receives the GUID value for the computed Conversation ID. On failure, the function returns E\_INVALIDARG.

The helper function ComputeMD5Guid(...) is provided here as a placeholder. It computes an MD5 hash of the contents of the buffer passed to the function, as specified in [RFC1321].

```

#define c_ulConvIndexIDOffset 6
#define c_ulConvIndexIDLength 16
#define cchMax 256

typedef struct {
    ULONG         i[2];
    ULONG         buf[4];
    unsigned char in[64];
    unsigned char digest[16];
} MD5_CTX;

void ComputeMD5Guid(byte *pbBuffer, ULONG cbBuffer, GUID *pguid)
{
    // Compute the MD5 hash of the contents of pbBuffer and return
    // in the pguid parameter.
}

HRESULT HrComputeConvID(
    byte *pbConvIndex,
    ULONG cbConvIndex,
    LPCWSTR pwzConvTopic,
    BOOL fConvTracking,
    GUID *pguidConvID
)
{
    HRESULT    hr = S_OK;
    BOOL      fUseTopic = TRUE;

    if (fConvTracking
        && NULL != pbConvIndex

```

```

    && cbConvIndex >= c_ulConvIndexIDOffset + c_ulConvIndexIDLength
    && 0x01 == pbConvIndex[0])
{
    memcpy(pguidConvID, pbConvIndex + c_ulConvIndexIDOffset, c_ulConvIndexIDLength);
    fUseTopic = FALSE;
}

if (fUseTopic)
{
    if (NULL != pwzConvTopic)
    {
        size_t cchHash;
        WCHAR wzBuffer[cchMax];
        size_t cbHash = 0;

        cchHash = wcslen(pwzConvTopic);
        if (cchHash < cchMax)
        {
            size_t ich;
            for (ich = 0; ich <= cchHash; ich++)
                wzBuffer[ich] = towupper(pwzConvTopic[ich]);
            cbHash = cchHash * sizeof(WCHAR);
            ComputeMD5Guid((byte *)wzBuffer, cbHash, pguidConvID);
        }
        else
            hr = E_INVALIDARG;
    }
    else
        hr = E_INVALIDARG;
}

return (hr);
}

```

## 5.5 Block Signature

The following is the algorithm to calculate the signature of a block. The signature is calculated by first obtaining the DWORD XOR result between the absolute file offset of the block and its BID. The WORD signature is then obtained by obtaining the XOR result between the higher and lower 16 bits of the DWORD obtained previously.

```

WORD ComputeSig(IB ib, BID bid)
{
    ib ^= bid;
    return(WORD(WORD(ib >> 16) ^ WORD(ib)));
}

```

## 6 Appendix B: Product Behavior

The information in this specification is applicable to the following product versions. References to product versions include released service packs.

- Microsoft® Office Outlook® 2003
- Microsoft® Office Outlook® 2007
- Microsoft® Office Basic 2007
- Microsoft® Office Standard 2007
- Microsoft® Office Small Business 2007
- Microsoft® Office Professional 2007
- Microsoft® Office Professional Plus 2007
- Microsoft® Office Enterprise 2007
- Microsoft® Office Ultimate 2007
- Microsoft® Outlook® 2010 with Business Contact Manager
- Microsoft® Outlook® 2010
- Microsoft® Office Standard 2010
- Microsoft® Office Home and Business 2010
- Microsoft® Office Professional 2010
- Microsoft® Office Professional Plus 2010

Exceptions, if any, are noted below. If a service pack number appears with the product version, behavior changed in that service pack. The new behavior also applies to subsequent service packs of the product unless otherwise specified.

Unless otherwise specified, any statement of optional behavior in this specification prescribed using the terms SHOULD or SHOULD NOT implies product behavior in accordance with the SHOULD or SHOULD NOT prescription. Unless otherwise specified, the term MAY implies that product does not follow the prescription.

[<1> Section 1.3.2.1.3:](#) Office Outlook 2007 with Service Pack 2 and Outlook 2010 do not use Free Maps and Free Page Maps.

[<2> Section 1.3.2.3:](#) Office Outlook 2003 and Office Outlook 2007 without Service Pack 2 do not use or create Density Lists.

[<3> Section 2.2.1.2:](#) Office Outlook 2003, Office Outlook 2007, and Outlook 2010 can read, write, and create both ANSI and Unicode PST files. The default format is Unicode.

[<4> Section 2.2.2.5:](#) Office Outlook 2003, Office Outlook 2007, and Outlook 2010 use this value for implementation-specific data. Modification of this value can result in failure to read the PST file by Outlook.

[<5> Section 2.2.2.5:](#) Office Outlook 2003 uses VALID\_AMAP1 to indicate that the AMaps are valid.

[<6> Section 2.2.2.5:](#) Office Outlook 2003, Office Outlook 2007, and Outlook 2010 use this value for implementation-specific data. Modification of this value can result in failure to read the PST file by Outlook.

[<7> Section 2.2.2.5:](#) Office Outlook 2003, Office Outlook 2007, and Outlook 2010 use this value for implementation-specific data. Modification of this value can result in failure to read the PST file by Outlook.

[<8> Section 2.2.2.6:](#) Office Outlook 2003, Office Outlook 2007, and Outlook 2010 use this value for implementation-specific data. Modification of this value can result in failure to read the PST file by Outlook.

[<9> Section 2.2.2.6:](#) Office Outlook 2003, Office Outlook 2007, and Outlook 2010 use this value for implementation-specific data. Modification of this value can result in failure to read the PST file by Outlook.

[<10> Section 2.2.2.6:](#) Office Outlook 2003, Office Outlook 2007, and Outlook 2010 use this value for implementation-specific data. Modification of this value can result in failure to read the PST file by Outlook.

[<11> Section 2.2.2.6:](#) Office Outlook 2003, Office Outlook 2007, and Outlook 2010 use this value for implementation-specific data. Modification of this value can result in failure to read the PST file by Outlook.

[<12> Section 2.2.2.6:](#) Office Outlook 2003, Office Outlook 2007, and Outlook 2010 use this value for implementation-specific data. Modification of this value can result in failure to read the PST file by Outlook.

[<13> Section 2.2.2.7.3:](#) Office Outlook 2003 and Office Outlook 2007 without Service Pack 2 do not use the Density List, and always use the PMap to locate free Pages.

[<14> Section 2.2.2.7.4:](#) Office Outlook 2003 and Office Outlook 2007 without Service Pack 2 do not create or use the Density List, and always use the PMap, FMap, and FPMMap to locate free Pages.

[<15> Section 2.2.2.7.5:](#) Office Outlook 2003 and Office Outlook 2007 without Service Pack 2 do not create or use the Density List, and always use the FMap to locate free Pages.

[<16> Section 2.2.2.7.6:](#) Office Outlook 2003 and Office Outlook 2007 without Service Pack 2 do not create or use the Density List, and always use the FPMMap to locate free Pages.

[<17> Section 2.4.8.4.2:](#) Office Outlook 2003, Office Outlook 2007, and Outlook 2010 modify the Search Activity List.

[<18> Section 2.6.1:](#) Office Outlook 2003 and Office Outlook 2007 without Service Pack 2 update and maintain PMaps.

[<19> Section 2.6.1:](#) Office Outlook 2003 and Office Outlook 2007 without Service Pack 2 update and maintain FMaps.

[<20> Section 2.6.1:](#) Office Outlook 2003 and Office Outlook 2007 without Service Pack 2 update and maintain FPMMaps.

[<21> Section 2.6.1:](#) Office Outlook 2003 and Office Outlook 2007 without Service Pack 2 do not create or use the DList.

[<22> Section 2.6.1.3.4:](#) Office Outlook 2007 with Service Pack 2 and Outlook 2010 implement backfilling.
